Frontal bone

- Vault of skull (Flat bones)
 - (Neurocranium)
- It develops from the **mesoderm** around the developing brain.
- These bones included the frontal, parietal, and occipital
- These bones ossified in membranes.

Occipital bone

dr_youssefhussein@yahoo.com

** The newborn skull

- The bones of the newborn skulls are separated from each other by sutures.
- At The meeting of more than 2 bones there is membranous parts called the **fontanelle.** They include: dr_youssefhussein@yahoo.com
- 1- Anterior fontanelle: between the frontal and 2 parietal bones. It is closed about 18 months (Bregma at adult).
- 2- Posterior fontanelle: between the occipital and 2 parietal bones. It is closed about 6 months (Lambda at adult).
- **3- Sphenoid fontanelle:** between the frontal, sphenoid, temporal and parietal bones. It is closed about 3 months (pterion at adult).
- 4- Mastoid fontanelle: between the occipital, parietal and mastoid part of temporal bones. It is closed about 3 months (asterion at adult).

Cribriform plate, of ethmoid bone

Body of sphenoid

Basilar part of occipital bone

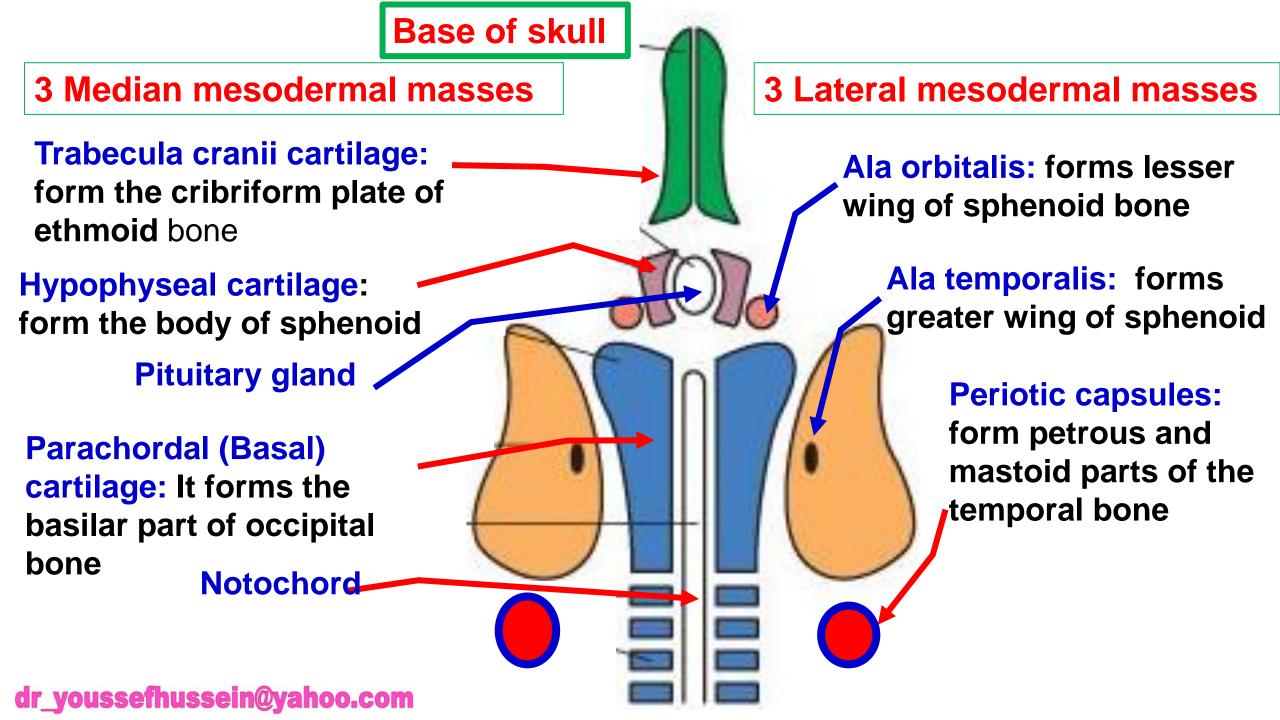

Constitution of the second

Lesser wing of sphenoid

Greater wing of sphenoid

Petrous part of temporal cone

 Microcephaly small skull and cerebral hemisphere

Hydrocephalus
excessive accumulation of
C.S.F in the ventricular
system due to closure in the
CSF circulation

Anencephaly:

failure of development of greater part of the brain and vault of the skull due to failure of cephalic part of the neural tube to close

- Meningoencephalocele herniation of a part of the brain and its covering meninges.
- Meningohydroencephalocele: herniation of the meninges and part of the brain and its ventricle containing CSF

<u>Meningoencephalocele</u>

Scaphocephaly: the skull is elongated anteroposterior due to early closure of the sagittal suture

Acrocephaly: high skull due to early closure of the coronal suture

Plagiocephaly: Asymmetrical shape due to early closure of the coronal and lambdoid sutures

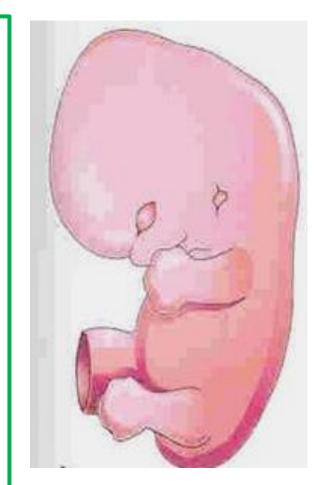

DEVELOPMENT OF THE LIMBS

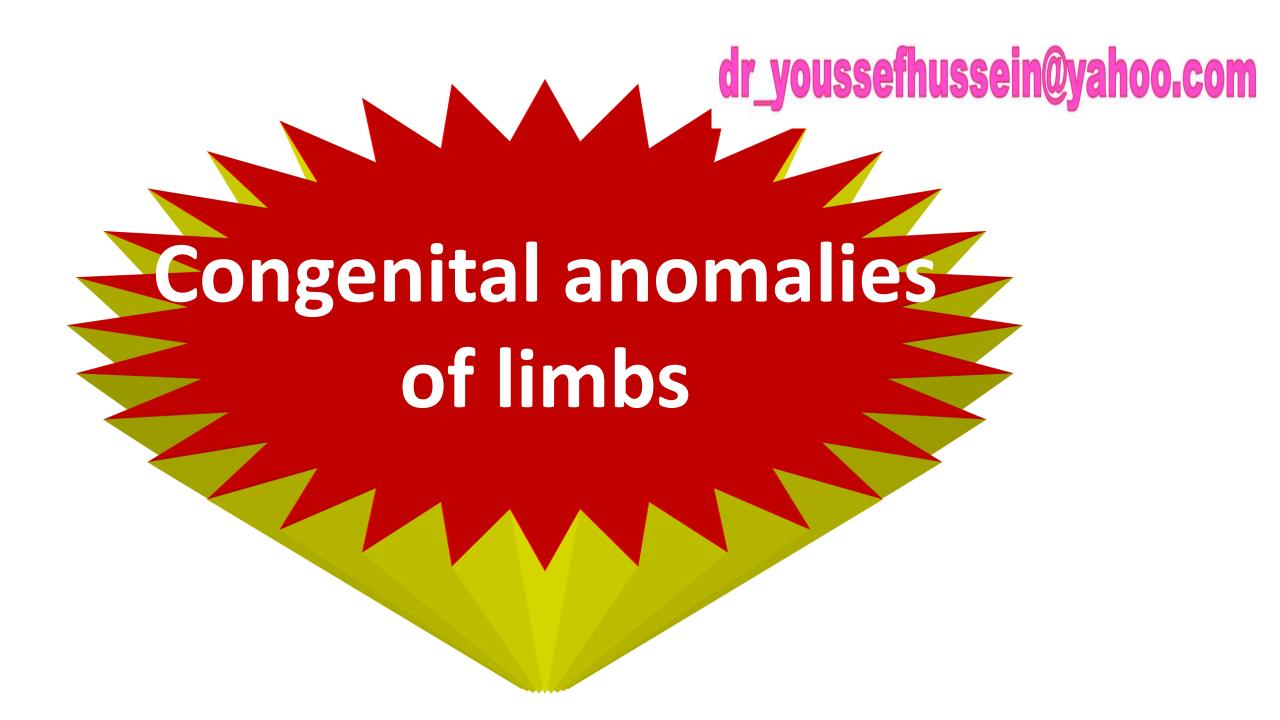

- * They develops as 4 buds (2 cranial and 2 caudal) at 4th week.
- * Each limb bud is formed of a mass of mesoderm, its central part changes into cartilage then into bone while the surrounding mesoderm forms the muscles.
- * The upper limb divides into arm, forearm and hand with 5 fingers.
- * The lower limb divides into thigh, leg and foot with 5 toes.
- * Each limb bud forms right angle (90 degree) with the trunk and has a preaxial border cranially (radius, and thumb for the upper limb and tibia and big toe for the lower limb) and a postaxial border caudally.

** Rotation of the limbs

- Upper limb rotates laterally so that the preaxial border (radius and thumb) becomes lateral and the flexor surface becomes anterior.
- * Lower limb rotates medially so that the preaxial border (tibia and big toe) becomes medial and the flexor surface becomes posterior.

Meromelia: The limbs represented only by foot or hand attached to the trunk

Amelia: Absence of one or more limbs

Micromelia: short segments of the limb

Lobster hand: A central fissure or cleft divides the hand or foot into 2 parts

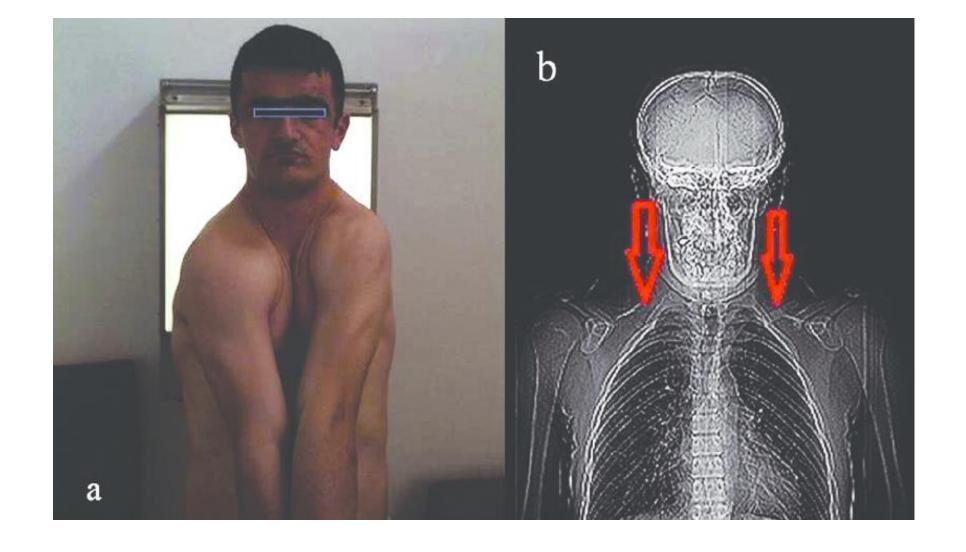

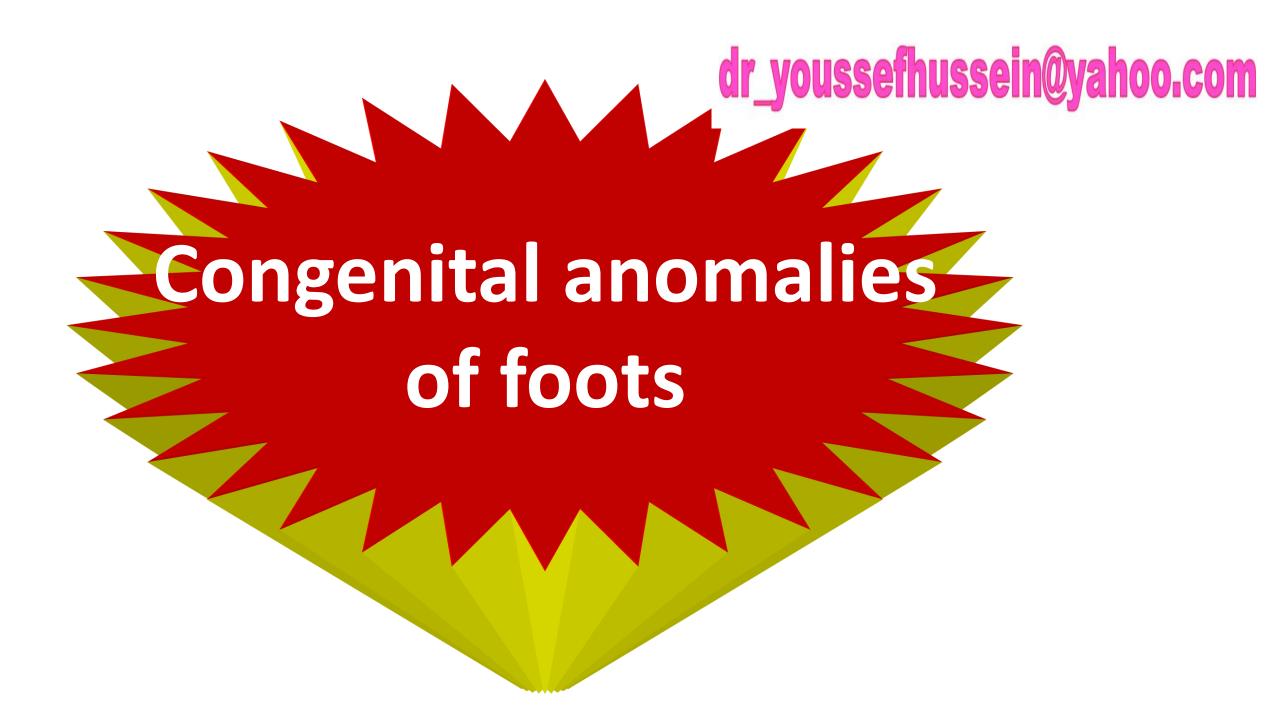

Polydactyl: Extra number of the fingers or toes.

Syndactyl: Abnormal fusion of the fingers.

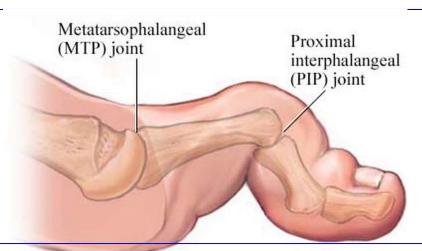

Congenital absence of some bones as clavicle

Flat Foot: loss of the arch of the foot

 Hammer Toe: extension of metatarsophalangeal joint and flexion of proximal interphalangeal joint.

Pes Cavus: Arch of the foot is high

 Hallux Valgus: lateral deviation of the big toe at the metatarsophalangeal joint. Talipes Equinus, permanent plantar flexion, walking is done on toes without touching the heel to ground

Talipes Calcaneus, permanent dorsiflexion, the heel rests on the ground and the toes pointed upwards

Talipes valgus: the sole of the foot inclined outward so that walking is done on the medial side of the foot

Talipes varus: the sole of the foot inclined inward so that walking is done on the lateral side of the foot
