The digestive system IV

Organs associated with digestive tract

- Liver
- Pancreas
- Gall bladder

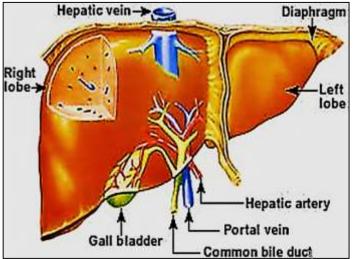

Liver

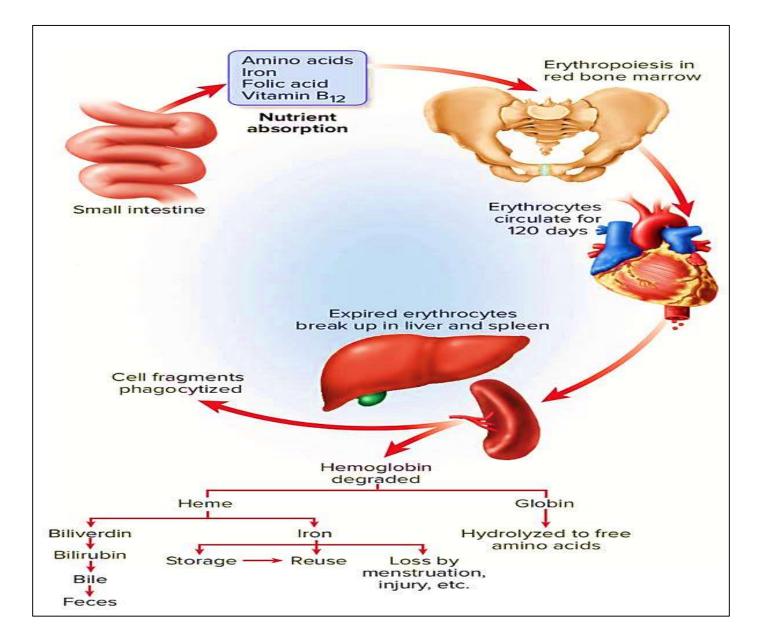

<u>Liver</u>

The Liver is the largest gland in the body (1.5 Kg) Mixed endocrine & exocrine gland

- 1. Processing & metabolism of nutrients
- 2. Detoxification: modifying potentially dangerous chemicals & removal of old RBCs
- 3. <u>Endocrine</u> : synthesize and secrete plasma proteins (albumin, prothrombin, fibrinogen), glucose &lipids into blood via blood sinusoids
- <u>Exocrine</u>: synthesize and secretion of bile
- 5- Storage of: glucose, fat , vit. A, B, D, K

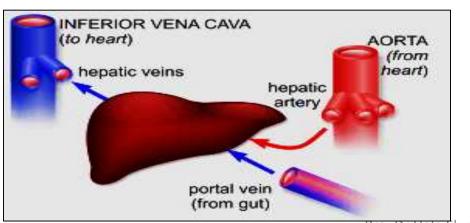

Pro. Dr Hala El- mazar

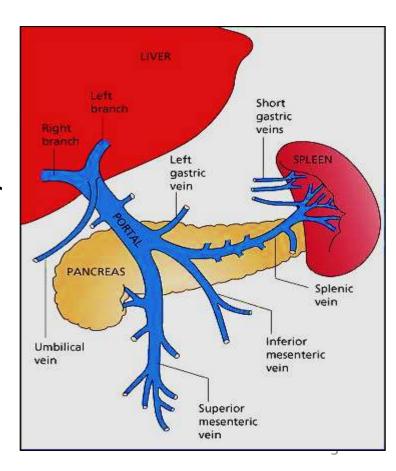

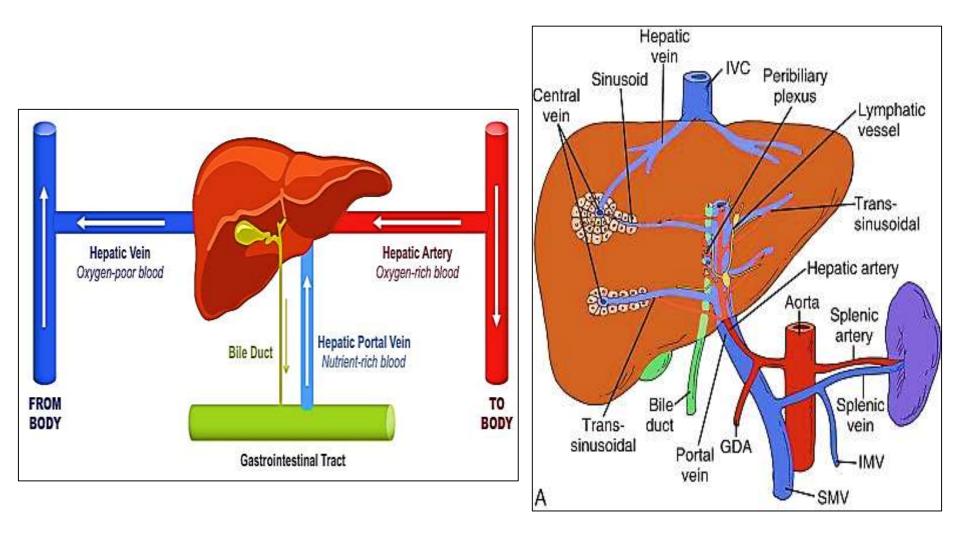

Blood supply of liver

1- Portal vein: 70 - 80%

- Main drainage of blood from GIT, spleen, pancreas
- Brings <u>nutrient rich</u>, <u>toxin loaded</u>, <u>oxygen poor</u> blood
- 2- Hepatic artery: 30 20%
 Aorta → hepatic artery
- Brings <u>oxygen rich</u> blood to liver

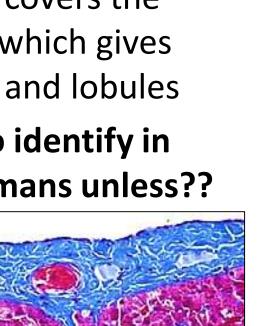

Blood supply of the liver

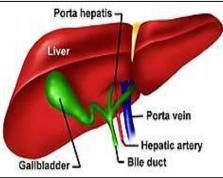

Structure of liver

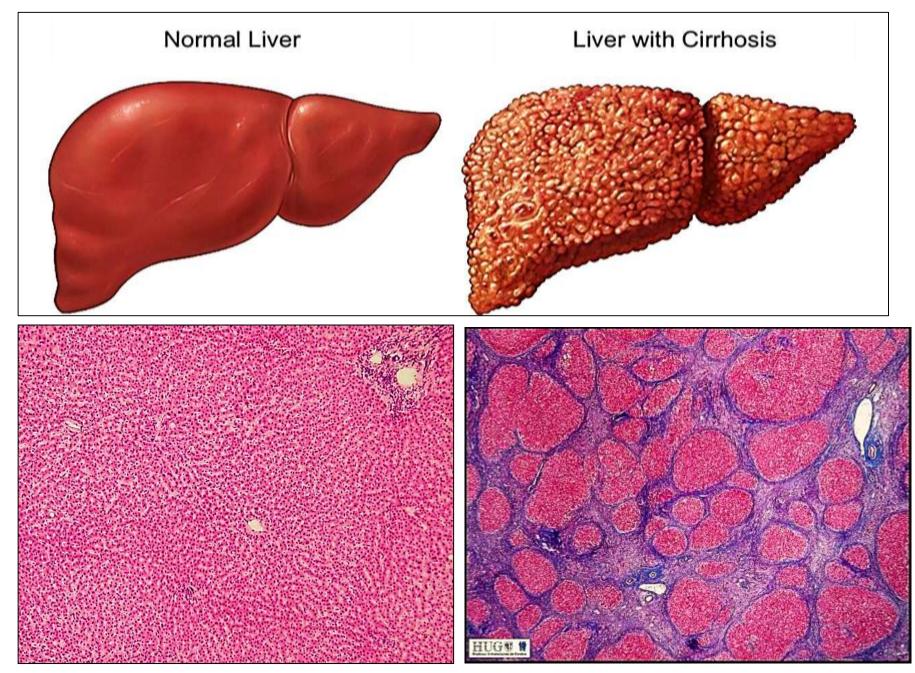

Stroma & parenchyma

A) <u>Stroma</u>: capsule \rightarrow septa \rightarrow reticular fibers

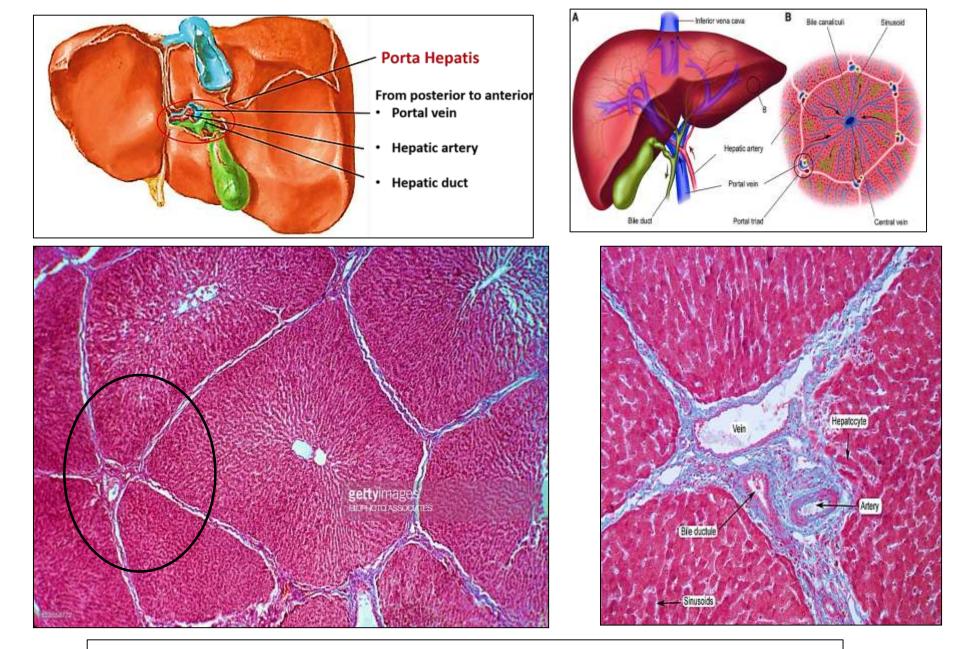

- Capsule of Glisson: thin fibrous C.T. sheet, covers the liver. Thick at hilum to form prota hepatis which gives rise to C.T. septa divide the liver into lobes and lobules
- septa: surround lobules. Thick and easy to identify in pig's liver.. Lobulation are not clear in humans unless??
- Portal tracts: triangular masses of
 C.T. at angles between hepatic lobules
- Reticular fibers: delicate network surround and support liver cells

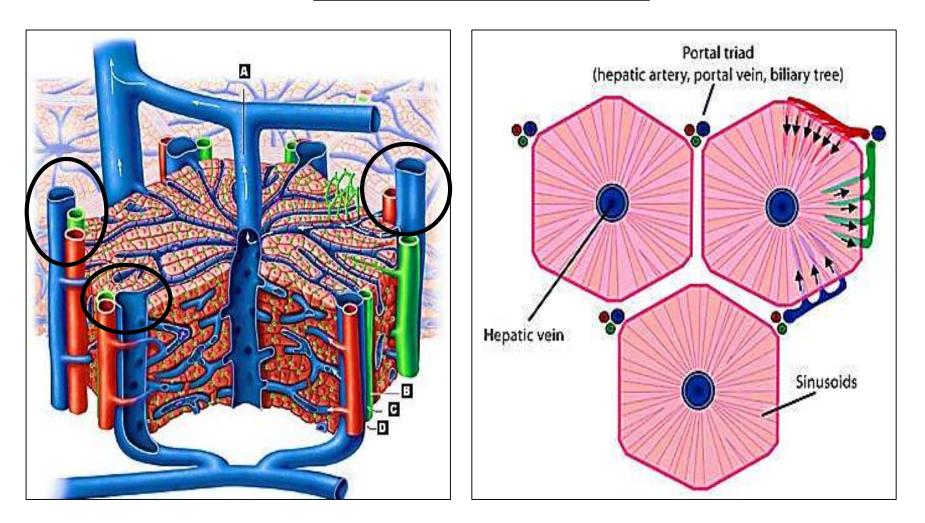

Pro. Dr Hala El- mazar

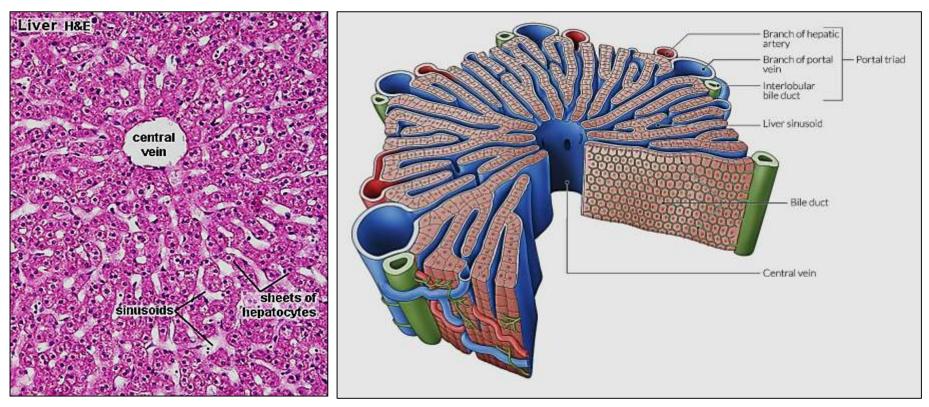

Septa are thick & the lobulation is clear in pig's liver (similar lobulation only seen in human's in liver cirrhosis)

Portal tracts of the liver

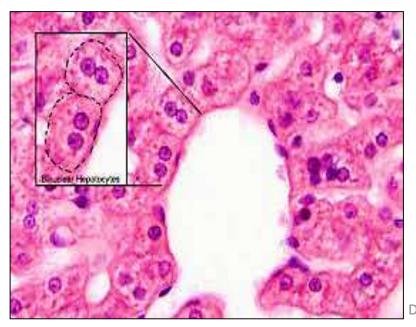

B) Parenchyma : Within each lobule the liver cells arranged in interconnected plates (cords) around the central vein

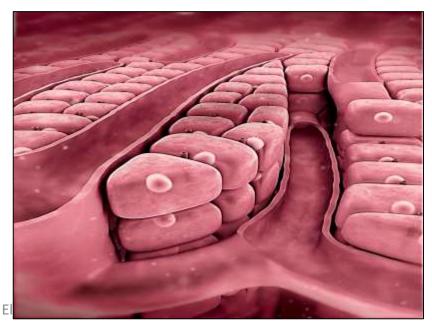

- The plates are two or more rows of cells width
- The spaces <u>between the plates</u> called liver sinusoids.
 They drain <u>blood</u> into central vein

Hepatocytes

- LM: large polygonal cells with 1 or 2 nuclei (bi-nucleated) so that they can more efficiently do all the required jobs. (The muscle cells have multiple nuclei)
- Nuclei: central, rounded, e prominent nucleoli

Cytoplasm is very rich in organelles & inclusions

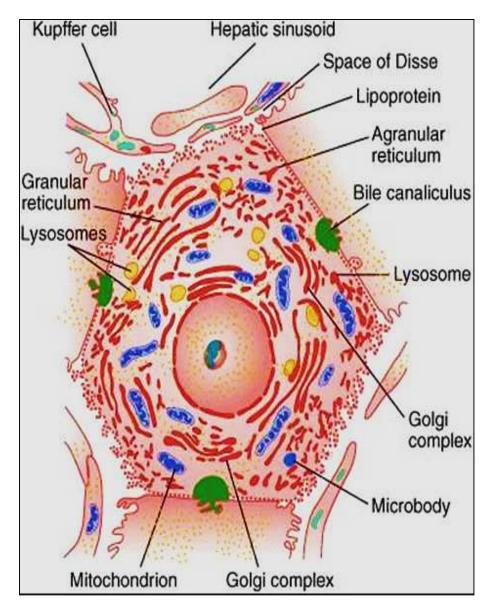

Organelles:

mitochondria, rER, ribosome, sER (detoxification, bile, glycogen), Golgi complex, lysosomes & peroxisomes.

Inclusions:

glycogen granules & fat droplets

Lipofuscin pigment (aged cells e.g cardiac ms. cells & nerve cells)

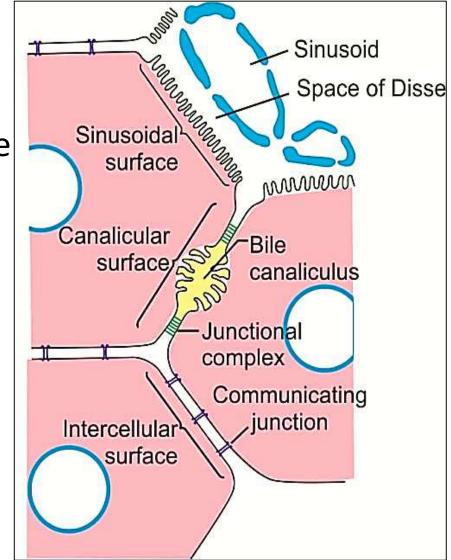

The hepatocytes has two functional surfaces:

1- the vascular side:

Has long microvilli and faces the perisinusoidal space (space of Disse)

2- The intercellular side:

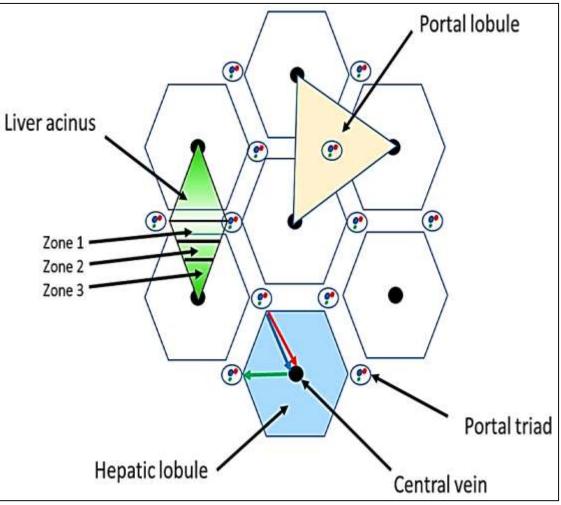

Has short microvilli projecting into the bile canaliculi and is bounded by tight junctions and desmosomes

Liver cells (hepatocytes) up to the Function they perform are arranged into either :

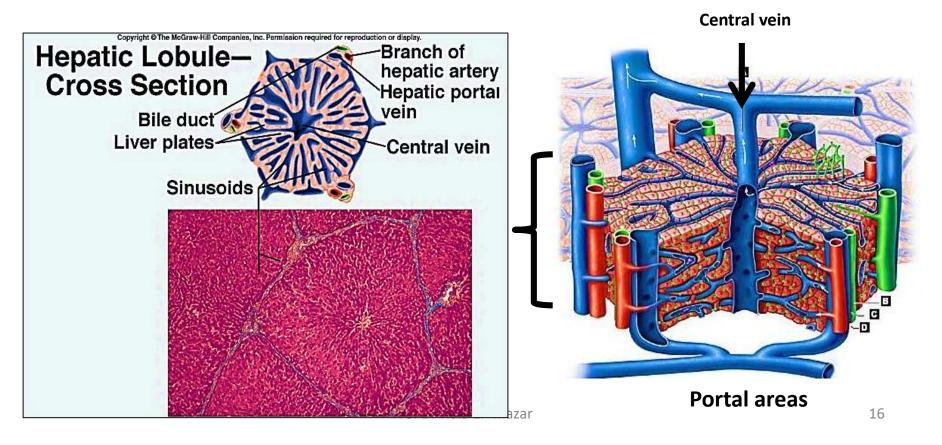

- 1- Classic hepatic lobule
- 2- Portal lobule
- 3- Liver acinus

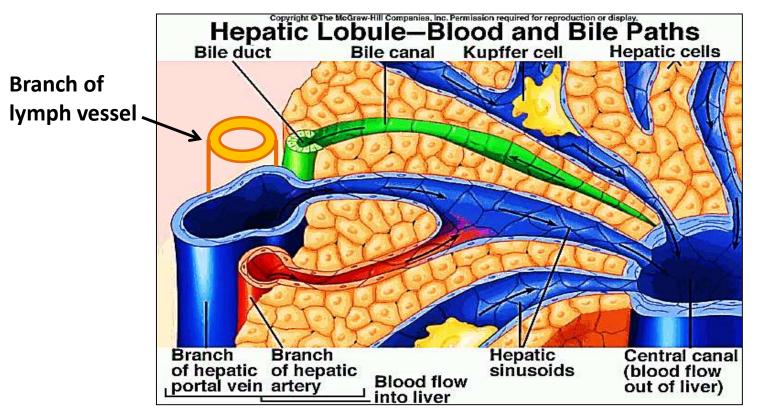

1- Classic hepatic lobule

- Hexagonal or polygonal in shape (cross section)
- Surrounded with thick C.T. septa in pig's liver
- Each lobule has 3-6 portal areas (portal triads) at its periphery, and central vein (CV) at its center

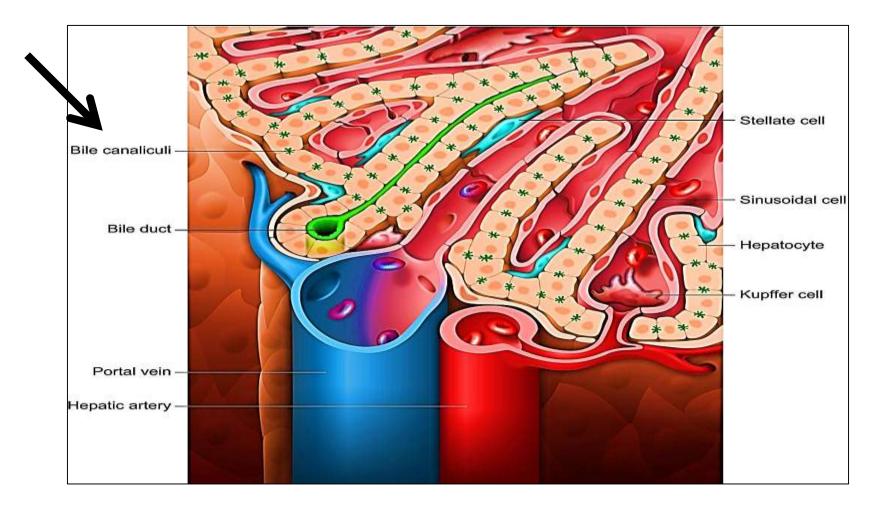

Portal areas (tracts): Each contains :

- 1. A branch of portal vein: widest with thin wall
- 2. A branch of hepatic artery: rounded with narrow lumen
- 3. A branch of bile duct: lined with cubical epithelium
- 4. Lymph vessel

 Bile canaliculi present within the plates in-between adjacent hepatocytes, they drain bile into the bile ducts in portal areas

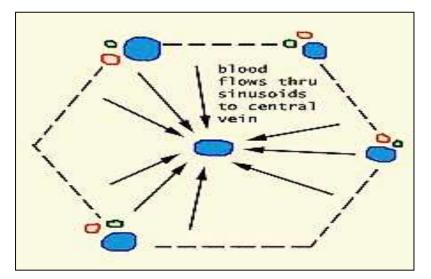

Liver sinusoids and space of Disse

A- Liver sinusoids

- Minute blood channels present <u>between</u> plates /cords of liver cells (hepatocytes never exposed to fully oxygenated blood)
- Transport blood from branches of portal vein & hepatic artery in portal area toward central veins (mixed blood)

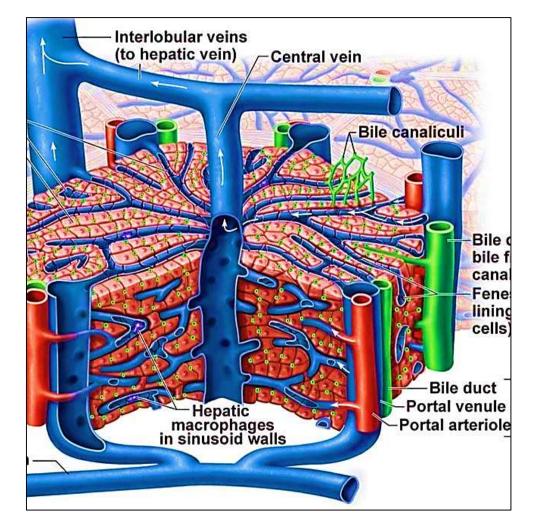

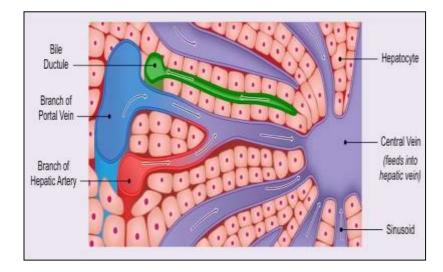

The flow of blood is centripetal

Drainage of liver sinusoids

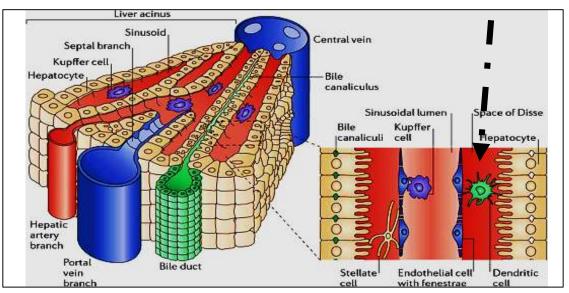

- Liver sinusoids \downarrow
- Central vein
 - \checkmark
- Hepatic vein
- Inferior vena cava
 ↓
- Right atrium of heart

- Lining of blood sinusoids consists of:
- ✓ fenestrated endothelial cells has no diaphragm
- ✓ Discontinuous basal lamina
- ✓ Kupffer cells
- ✓ Pit cells

 The wall of the sinusoids is separated from the hepatocytes by a space called space of Disse

Endothelial cells lining of liver sinusoids:

Kupffer g

 Flat cells, contain many holes (fenestrae) to allow free passage of molecules between blood and peri-sinusoidal space of Disse

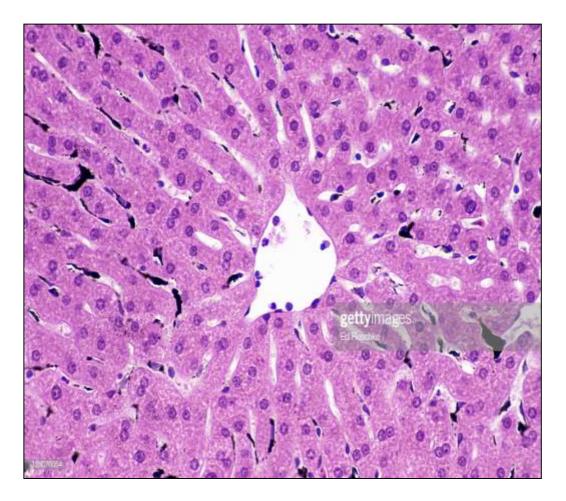

Hepatocyte

Stellate cell

<u>Kupffer cells:</u>
 Macrophages (Fixed) , large cells with large oval nucleus and numerous cytoplasmic processes. Seen in the blood sinusoids and in between endothelial cells. Their cytoplasm contain lysosomes, pinocytotic and phagocytic vesicles.

Blood vessel

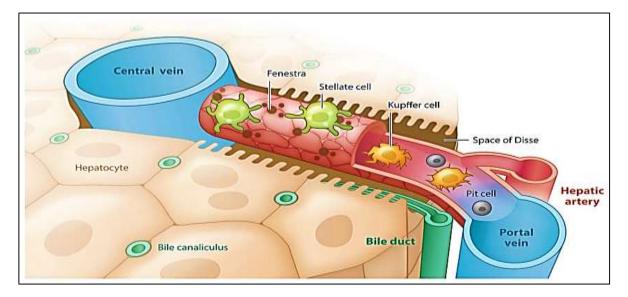

Endothelial cell

Kupffer cells seen in liver lobules as black cells with special stains (India ink). Found more near <u>portal areas</u>

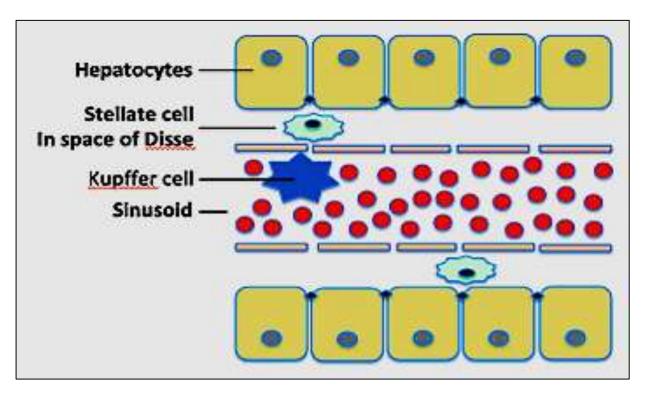

Pit cells: are liver-specific, short lived natural killer (NK) cells also called large granular lymphocytes (LGL). localized inside the lumen of the sinusoid, closely adhering to the endothelial cells and Kupffer cells, and often extending well-developed pseudopodia suggestive of migration along the sinusoidal wall. Multivesicular dense granules are frequently found in the cytoplasm of pit cells which exert antitumor functions by exocytosis of perforin/granzymecontaining granules, which cause death of target cells through receptor-mediated apoptosis, and production of various cytokines that augment the activities of other immune cells.

Safeguard liver cells against hepatitis virus infection or malignancy transformation

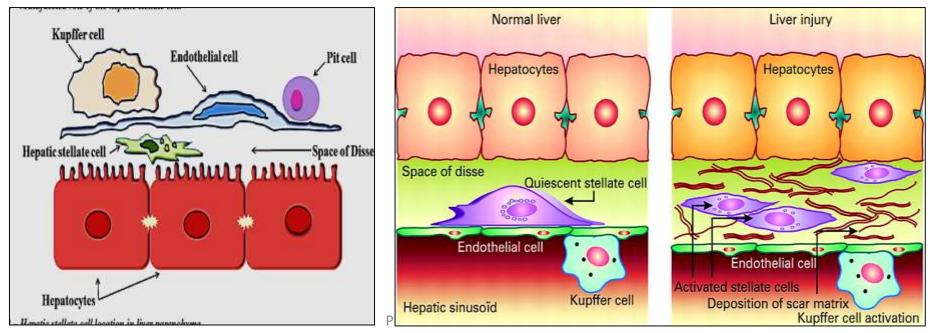

Space of Disse

- <u>EM</u>: Narrow space separate between the endothelial cells lining of the sinusoids and hepatocytes
- Through out the space exchange of metabolites between blood and hepatocytes takes place

Space of Disse contains:

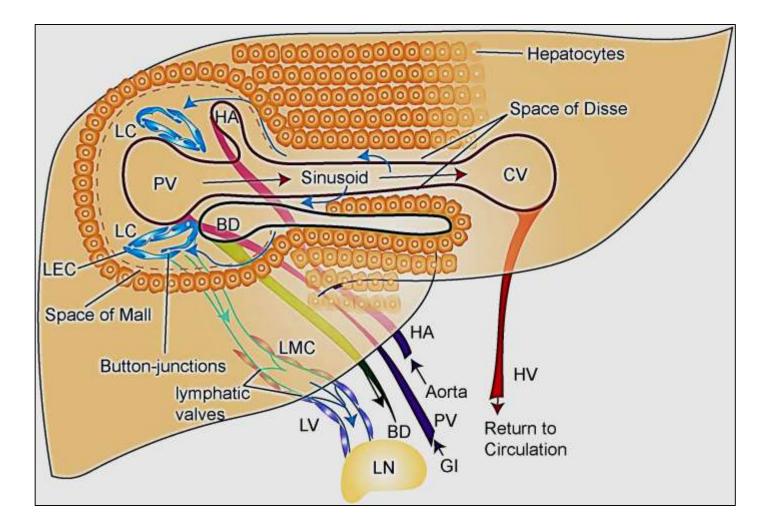

- Fat storing cells (Ito cells, stellate cells). They store Vit. A in small lipid droplets in their cytoplasm, and maintain the extracellular matrix of the space
- Long microvilli of hepatocytes project in the space (\uparrow)
- Blood plasma
- Reticular fibers that support the wall of the sinusoids

Ito cells:

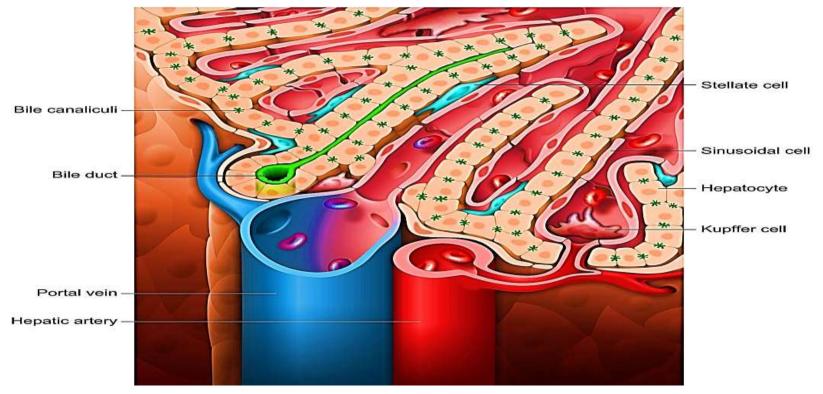

- Ito cells (perisinusoidal fat-storing cells, stellate cells, lipocytes) of the liver are located in the space of Disse.
- They are the main place of vitamin A storage in characteristic lipid droplets.
- In chronic inflammation of the liver on (e.g. viral hepatitis & Bilharziasis) they differentiates into myofibroblasts and deposit large amounts of collagen in the space of Disse causing liver fibrosis → ↑ portal hypertension → esophageal varices (famous singer death)

• The peri-sinusoidal spaces of Disse is the beginning of the lymphatic system of the liver

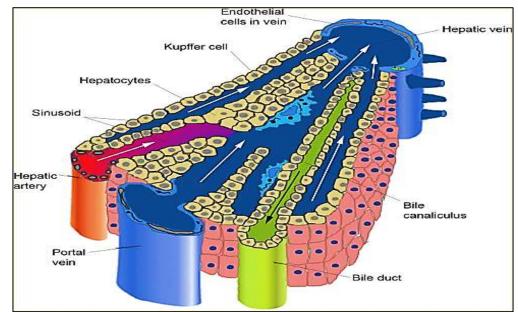

Bile canaliculi and bile ducts

- Minute canals present <u>within</u> hepatic plates, in-between adjacent hepatocytes.
- They are bounded by the cell membrane of adjacent hepatocytes

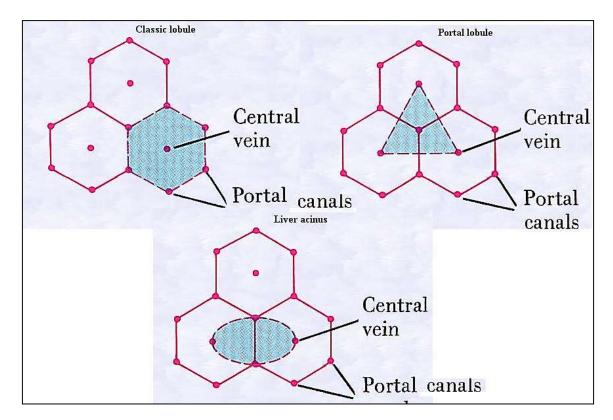

- Small microvilli project from hepatocytes into the canaliculi and tight junctions hold the cell membranes of hepatocytes around the lumen of the canaliculus (hepatocyte polarization)
 Sinusoidal/Basolatera membrane
- Bile secreted by hepatocytes drains out of the lobule.

Organization of liver parenchyma/function:

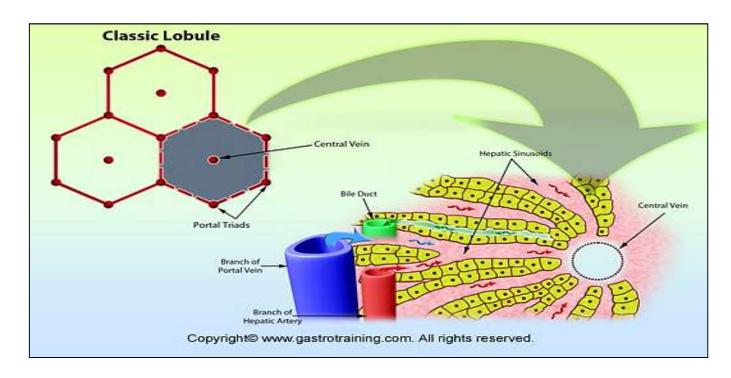

- Classic hepatic lobule \rightarrow endocrine function
- Portal lobule \rightarrow exocrine function
- Liver acinus \rightarrow oxygen/ nutrients supply

Classic hepatic lobule:

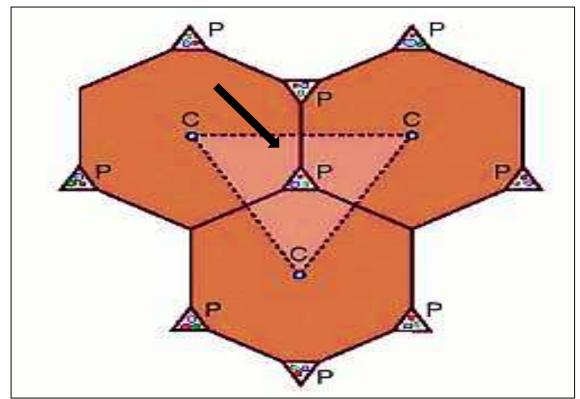

Hexagonal in shape with <u>central vein</u> in the center, surrounded with 3 – 6 portal tracts at the its corners

Proteins, glucose secreted by liver cells released directedly into blood sinusoids

Portal lobule:

- Triangular in shape, centered on **portal area (tract**) apices of the triangle are formed by 3 central veins.
- Hepatocytes of this lobule drain their bile to a bile duct in the center of the triangle

Liver acinus: is the most important classification

Diamond shaped mass of liver cells surrounding a central vascular core

It is divided into 3 zones:

Zone 1:

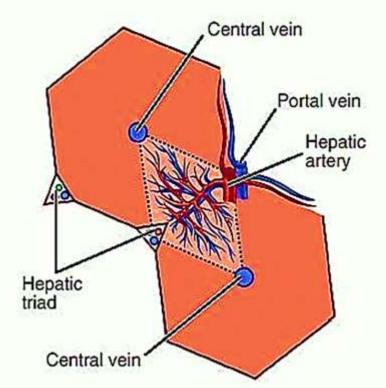

- Close to the vascular core
- Get the most oxygen and nutrients

Zone 2:

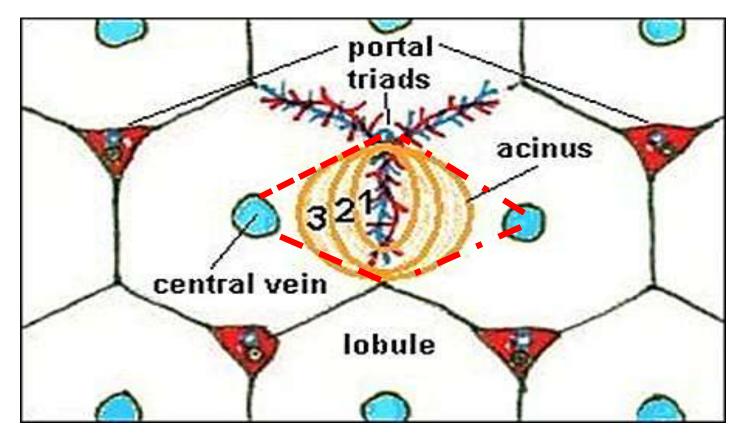

- Surrounds zone 1
- Get intermediate oxygen /nutrients

Zone 3:

- At the periphery near the central vein
- Get the least oxygen/ nutrient supply

Liver acinus

Arrangement of liver acinus explains the variation in liver cells damage in response to hypoxia & toxins.

zone 1

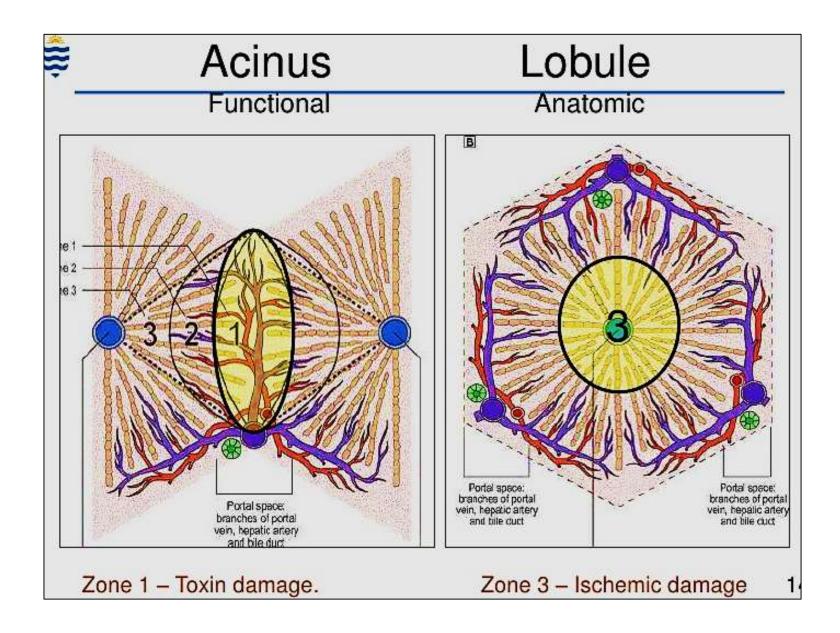

Cells <u>close</u> to the distributing vessels

- higher in : oxygen, nutrient & toxin levels
- Least susceptible to ischemia
- first to show changes following <u>bile duct occlusion</u>
- last to die due to <u>circulatory impairment</u>
- first to regenerate

zone 3

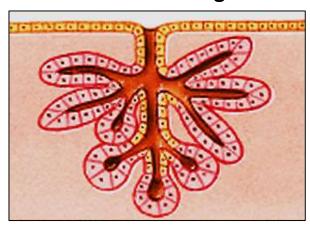

Cells <u>far from</u> the distributing vessels

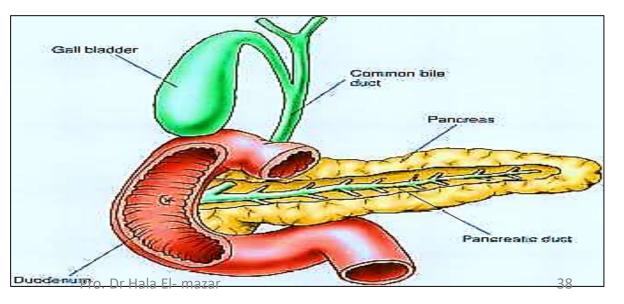

- first to show ischemic necrosis (death due to reduced circulation (centri-lobular necrosis)
- first cells to show fatty accumulation (alcoholic liver disease) because these cells important for glycolysis
- last to respond to toxins

Pancreas

- Mixed exocrine + endocrine gland produce both digestive enzymes and hormones
- <u>The exocrine part</u>: compound tubulo-alveolar gland secretes pancreatic enzymes & bicarbonate
- <u>The endocrine part</u>: <u>Islets of Langerhans</u> secrete hormones: insulin, glucagon, somatostatin..etc

Tubulo-alveolar gland

Structure of Pancreas

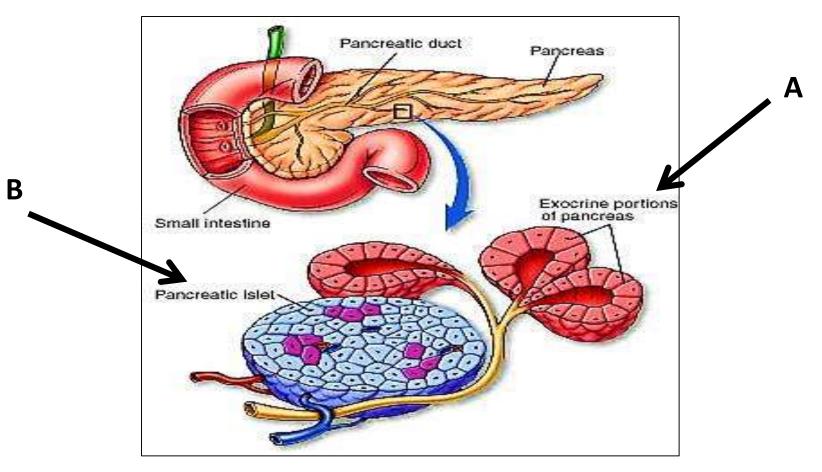

Stroma & Parenchyma

Stroma:

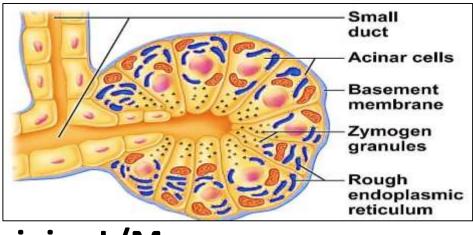

- **Capsule**: thin C.T sheath covers the Pancreas
- **Septa** (trabeculae): arise from the capsule, divide the organ into lobes and lobules
- Reticular fibers: delicate network of fibers support the parenchyma, rich with blood supply. Stained e sliver

Parenchyma:

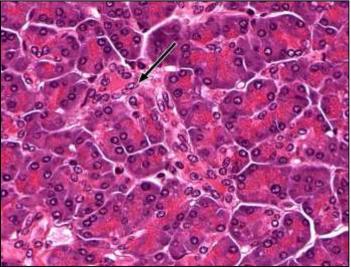

A- Exocrine part (acini & ducts) B- Endocrine part (islets of Langerhans)

A- Exocrine part: formed of acini & duct system

<u>Acini</u>: L/M

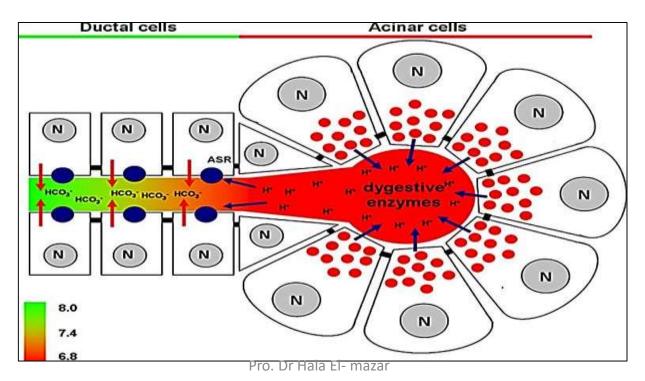

- Composed of <u>serous</u> producing cells (enzymes)
- The pancreatic acini has very small lumen
- Cells are pyramidal with rounded basal nuclei
- Cells are protein secreting cells \rightarrow (exocytosis)
- Cytoplasm shows basal basophilia (rER) & apical acidophilia (zymogen granules)

Pancreatic exocrine secretion is controlled by hormones from the endocrine cells of GIT (stomach & duodenum) : Cholecytokinin: ++ acinar cells to secrete pancreatic

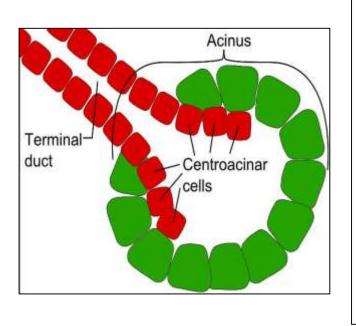

enzymes.

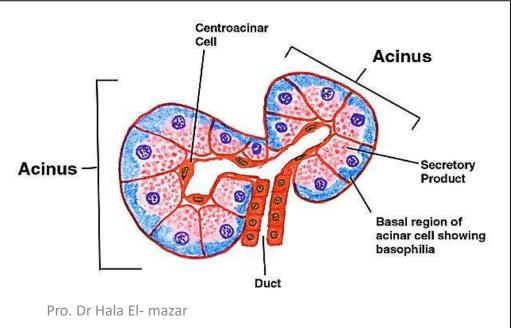

Secretin: ++ intercalated duct cells to secrete alkaline fluid to neutralize acidic chyme in duodenum.

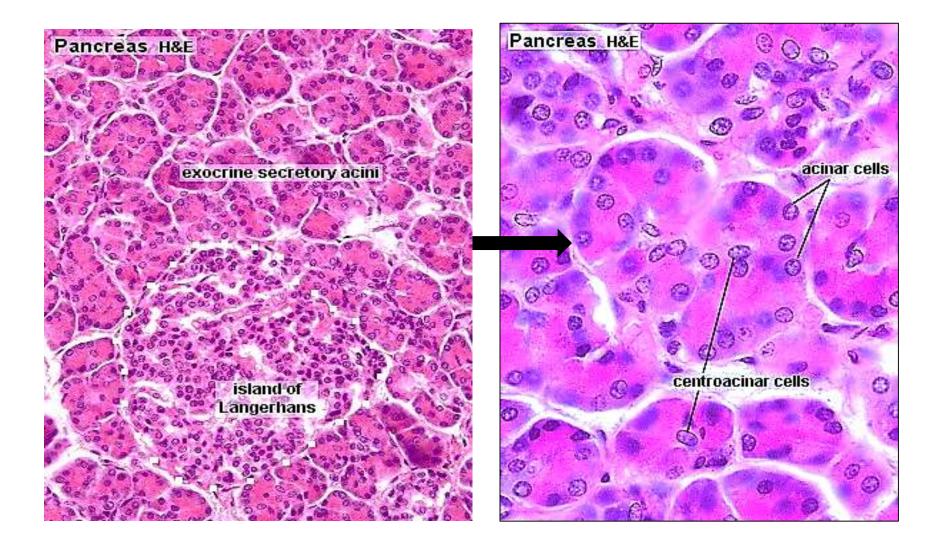

Centroacinar cells:

- Flat squamous cells found lining the lumen of the acini
- They represent the beginning of the cells o intercalated duct into
- They secrete bicarbonate rich fluid in response to secretin

Section in the pancreas showing the exocrine acini & the endocrine islets of Langerhans

Section in pancreas showing centroacinar cells

Duct system

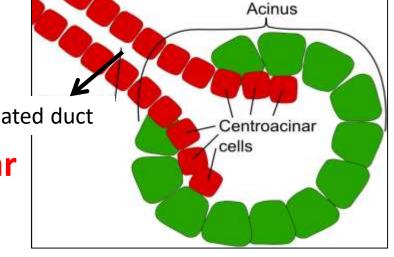

Intercalated ducts:

- Thin ducts arise from within the acini
- Lined with simple squamous cells.
- The initial cells called centroacinar cells (secrete HCO3 rich fluid which hydrate and alkalinizes the enzymatic secretion of acinar cells) Acinus

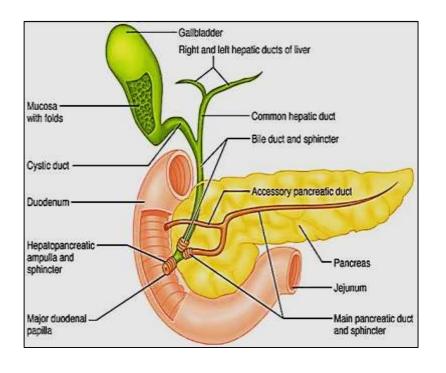

No striated ducts in the pancreas

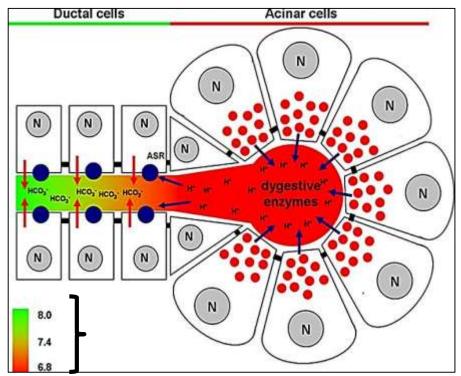

Intercalated duct

There are interlobular & interlobar ducts

Main duct: lined with columnar epithelium+ goblet cells + enteroendocrine cells

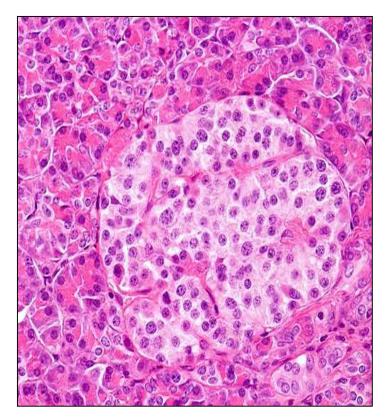

Function of exocrine pancreas:

1- It secretes pancreatic juice rich in **bicarbonate & digestive enzymes** (protease, amylase, lipase, nucleases,...)

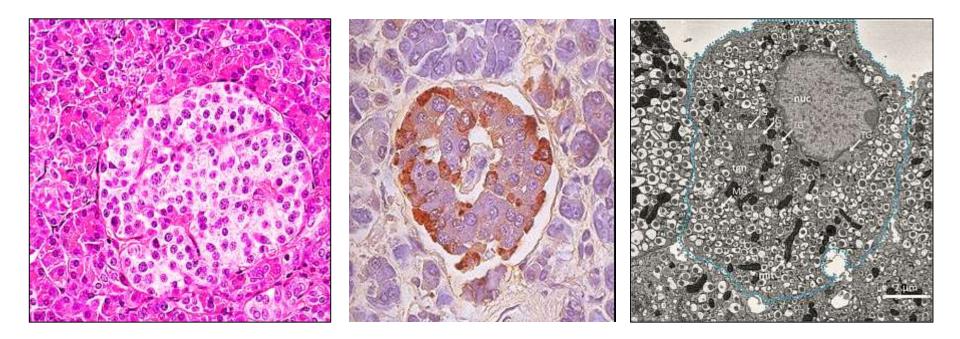

B- Endocrine part:

Islets of Langerhans

- Masses of pale staining cells scattered between the pancreatic acini
- They are more in the tail than head of pancreas
- The cells are separated by fenestrated capillaries (highly vascularized)
- Nerve supply autonomic nerve fibers
- Cells of islets of Langerhans are Alpha, Beta, Delta, Ganglion, PPcells

- Histological techniques to differentiate between the different types of pancreatic islets cells are:
- 1- Histochemistry
- 2- Immunohistochemistry
- 3- Electron microscope (secretory granules)

Beta (B) cells (70%):

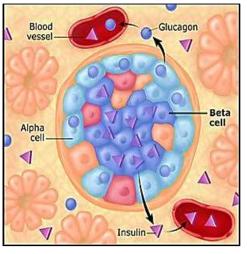

- Produce **insulin h** that **lower** blood sugar
- Cells are small in size, most numerous cell type, central in location in the islets
- Cells divide at very slow rate
- Beta cells secret C- peptide at the same time they sec. insulin.
- <u>C-peptide is a sign that your body is producing insulin</u>

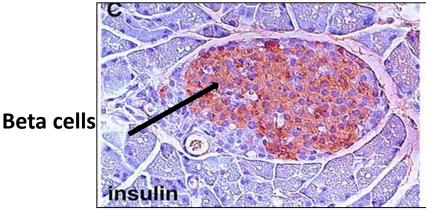

It prevents neuropathy and vascular problems.

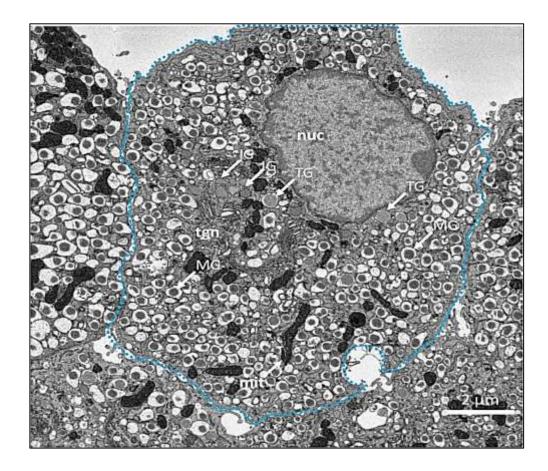

C- peptide is used as a marker in diabetic patients to evaluate the amount of functional B cells

- B cells secretes GABA which
- suppress glucagon secretion

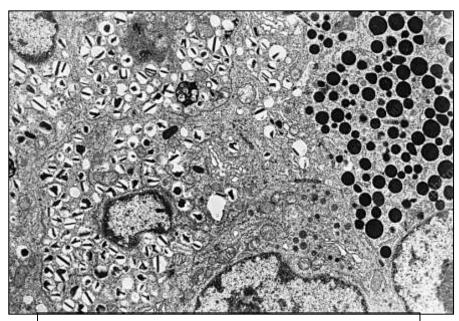

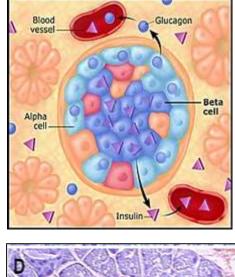

With EM the secretory granules that contain insulin inside B cells have a unique appearance have a rectangular crystalline dense core surrounded by an electro lucent halo

Alpha (A) cells (15%):

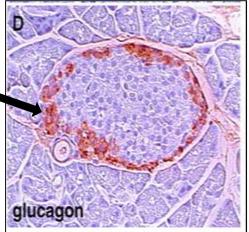

- Produce glucagon H that increases blood sugar
- Cells larger in size, fewer in number, peripheral location in Islets
- EM the secretory granules are numerous with homogenous dense core

Insulin granules vs glucagon granules

Alpha cells

Pro. Dr Hala El- mazar

Delta cells:

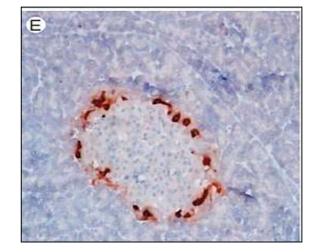

- Secret somatostatin (growth inhibiting factor) ↓ other hormones (insulin & glucagon)
- Cells scattered at periphery and less abundant Delta cells

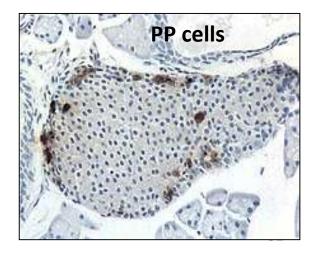

Ganglion cells:

 Aggregation of nerve cells for autonomic nervous control of islets secretion

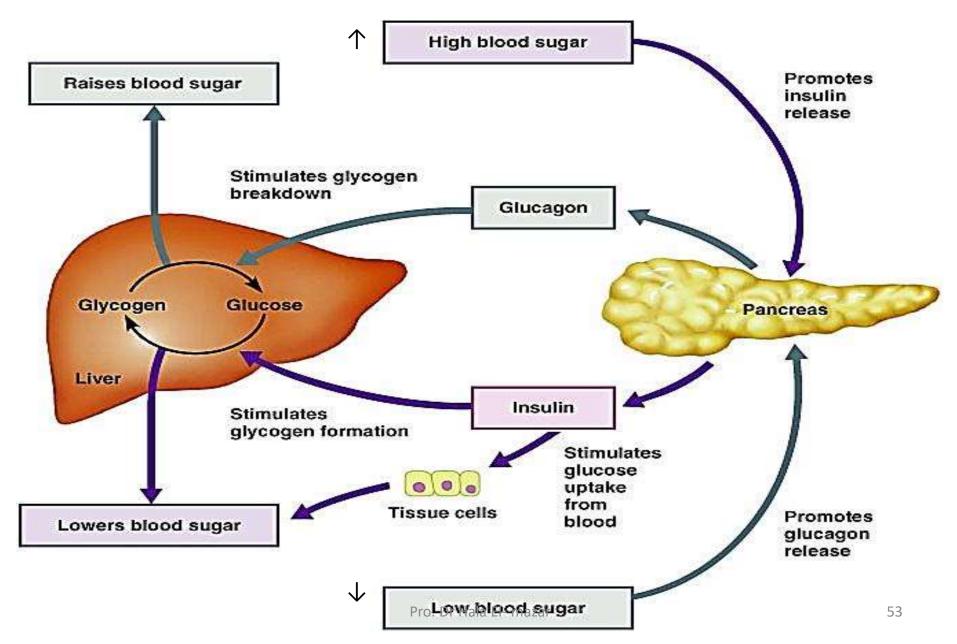

F (PP) cells (most peripheral)

- Very few
- Secrete pancreatic polypeptide h.
- Regulate exocrine pancreas secretions

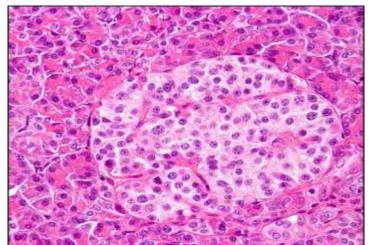

Regulation of blood glucose level

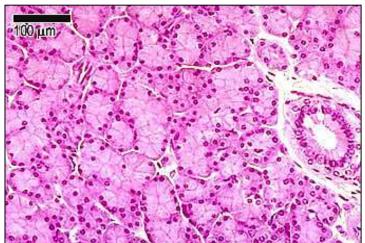

Pancreas vs. Parotid

Pancreas

- Capsule: thin
- Trabeculae: thin, loose
- Ducts: few, NO striated secretory ducts inside the lobules
- Acini: larger
 Centroacinar cells in lumen
- Islets of Langerhans: present

Parotid

- Thick
- Thick
- Abundant, striated secretory ducts are prominent inside the lobules

Smaller No centroacinar cells

Abscent

Hala Fl- maza

Gall bladder & biliary tract

- Hollow pear shaped organ
- Attach to the lower surface of liver
- It stores and concentrate bile secreted by liver
- Wall of gall bladder consists of:

Mucosa: (highly folded)

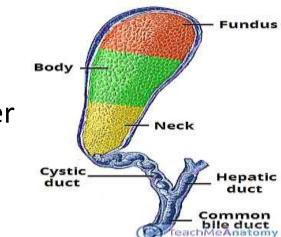

epithelium: simple columnar with microvilli

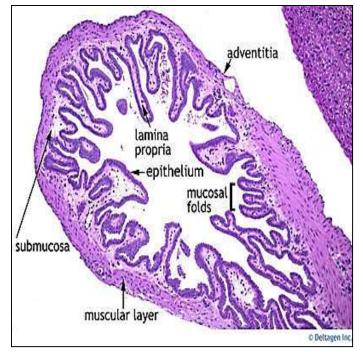

No muscularis mucosa

<u>Musculosa</u>

Bundles of irregularly arranged smooth m. Fibers , elastic & collagenous fibers

<u>Serosa</u>

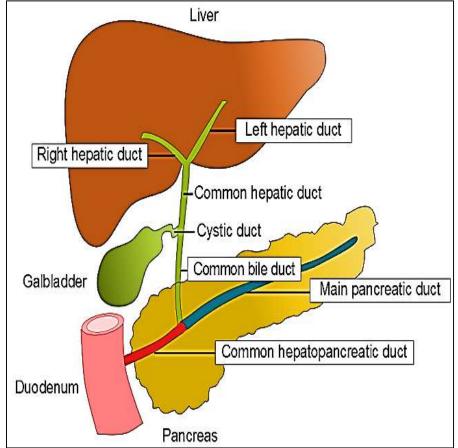

Biliary tract:

- Bile canaliculi \rightarrow bile ductules (canals of hering)
- \rightarrow bile ducts \rightarrow hepatic ducts (RT & LF hepatic ducts)
- ightarrow common hepatic duct ightarrow merge with cystic duct
- \rightarrow common bile duct
- \rightarrow merge with pancreatic duct \rightarrow ampulla of Vater
- \rightarrow open in duodenum

Liver regeneration: Liver cells have high regeneration capacity

Thank you
