

# pyramidal tract:

**Functions of the pyramidal tract:**  
 1- It initiates and facilitates isolated skilled voluntary movements, specially those which need training and educations as writing, threading a needle, typing.  
 2- It increase muscle tone and other deep reflexes.  
 3- It inhibits the ~~primitive~~ withdrawal reflex (Babinski's sign).

## Function

Most probably vascular (thrombosis or hemorrhage) or may be due to tumors or traumatic causes.  
 most common site in internal capsule or medulla.

## Lesions of the pyramidal tract:-

- 1- Loss of skilled voluntary movements (paralysis) in **opposite side = hemiplegia**.
- 2- Pure pyramidal lesion without other extra-pyramidal lesions -causes **hypotonia**.
- 3- Appearance of **Babinski's sign** (dorsiflexion of big toe).

## Information

It contains about one million fibers

- 60 % of them are myelinated (by oligo dendro glial cell in CNS)
- 40% are non myelinated.

fibers arise from

- 30 % from the primary motor area "4"
- 30 % from the pre-motor area "6"
- 40 % from somatic sensory area (areas 3,1, 2 and area 5,7).

one way, direct connection between UMN and AHC (one neuron)

These cells are never found in any other area except in area (4).

only tract which contains the axons of certain cells called "the Pyramidal" or Betz " cells which are found in the 5th layer in the motor area "4".

this myelination becomes complete one year after birth

## المحطات

which occupies the anterior 2/3 of the posterior limb of the internal capsule.

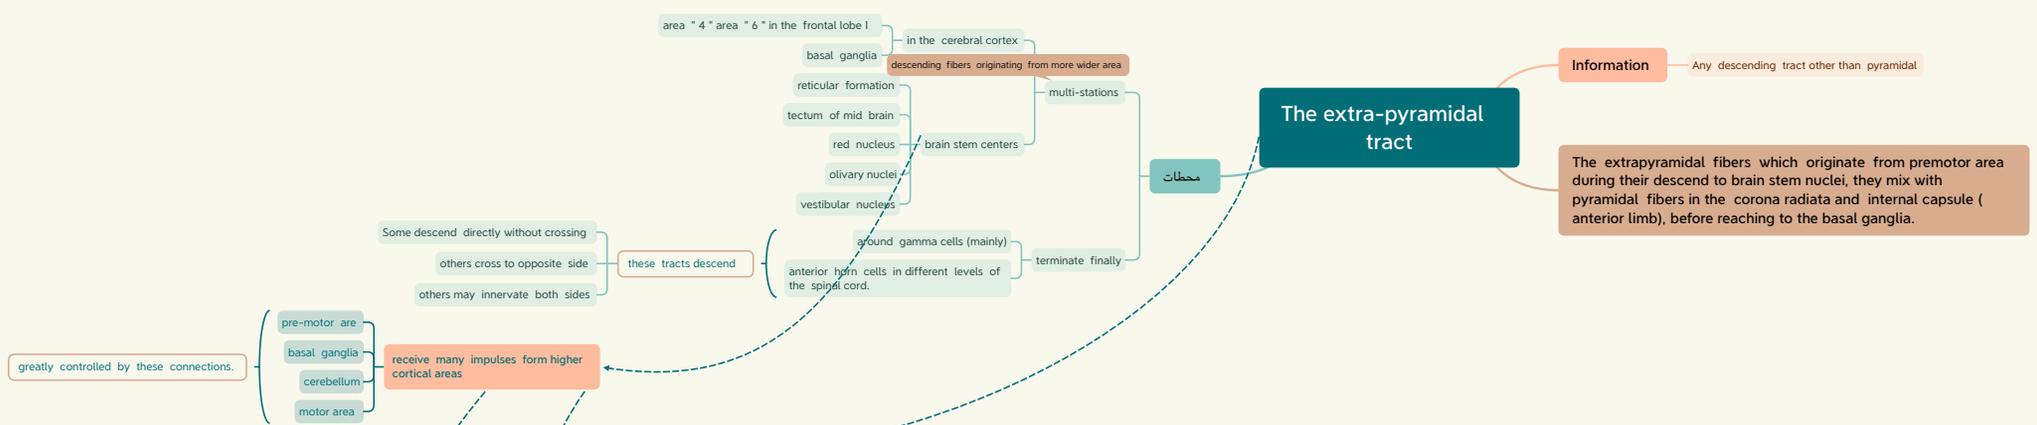

Cerebral cortex — axons of the tract form in the cortical area what is called the "corona radiata"

midbrain — fibers of the tract are grouped in bundles  
 — it from 3/5 of basis pedunculi

pons — descends in the basis pontis

medulla — they f from specif ic elevations called the " pyramid ".

Type	The cortico-spinal tract	The cortico-bulbar tract	the cortico-nuclear tract.
Cerebral cortex	Cerebral cortex — Pyramidal" or "Betz" cells in area (4).	Cerebral cortex — lower parts of area " 4 " and " 6 "	Cerebral cortex — originates form specific area called " frontal eye field " or area " 8 "
Brain stem	Brain stem ( in medulla) <ul style="list-style-type: none"> <li>80% cross to the opposite side forming motor decussation</li> <li>20% of fibers descends in same side</li> </ul>	brain stem <ul style="list-style-type: none"> <li>Large part of fibers cross to opposite side</li> <li>explains little affection of the face in internal capsule lesion.</li> <li>many fibers innervate same side</li> </ul>	Brain stem — (medial longitudinal bundle). <ul style="list-style-type: none"> <li>supplies the specific cranial nuclei of both sides</li> <li>innervate the nuclei of III, IV , and VI</li> </ul>
Finally	Spinal cord <ul style="list-style-type: none"> <li>forming the lateral cortico-spinal tract — ends around interneurons and A.H.C at different levels of the spinal cord segments.</li> <li>forming direct or ventral cortico- spinal tract — re-cross to the opposite side in different levels in cervical and thoracic regions to end around A.H.C.</li> <li>1% of fibers descend directly without crossing forming Ipsilateral cortico-spinal tract — same side AHC.</li> </ul>	terminates on motor nuclei of cranial nerves <ul style="list-style-type: none"> <li>that supply muscles and glands of head &amp; neck</li> <li>cranial nerves number (V, V II , I X , X , X I and X II ).</li> <li>innervated only from opposite pyramidal tract.</li> <li>All hypoglossal nucleus (supply toungue) and lower 1/2 of facial nucleus</li> </ul>	innervate the nuclei of III, IV , and VI <ul style="list-style-type: none"> <li>which supplies the extra-ocular muscles.</li> <li>performs conjugated deviation of both eyes to opposite side</li> <li>accommodation to near and far vision</li> </ul>

Type	المشأ	العريق	النهاية
A) Reticulo-spinal tracts:-	arise from reticular formation in the brain stem	then divides into <ul style="list-style-type: none"> <li>Medial reticulo-spinal tract= ventral               <ul style="list-style-type: none"> <li>arises from pontine reticular formation</li> <li>descends without crossing (direct)</li> <li>facilitatory to muscle tone</li> </ul> </li> <li>Lateral reticulo-spinal tract =dorsal               <ul style="list-style-type: none"> <li>arises from medullary reticular formation</li> <li>crosses to opposite side</li> <li>inhibitory to muscle tone</li> </ul> </li> </ul>	end mainly around A.H.C
B) Vestibulo-spinal tract:	carries the pathways of postural reflexes arising from the labyrinth arises from vestibular nucleus to A.H. cells	divides into <ul style="list-style-type: none"> <li>lateral</li> <li>medial</li> </ul> no crossing (direct) facilitatory to muscle tone specially extensors (antigravity muscles )	ends at different levels of the spinal cord.
C) Rubro-spinal tract: -	from red nucleus in mid brain	The tract crosses rapidly in midbrain to the opposite side. inhibitory to muscle tone (interneuron)	controls many muscle activities through special tract called " cortico-rubro- spinal system".
D) Olivo-spinal tract:	It arises from the inferior olivary nuclei in the medulla	descends without crossing (direct) causing facilitation to muscle tone.	is relatively short tract ends around A.H.C till the cervical region only
E) Tecto-spinal tracts :-	Lateral from superior colliculus of the mid brain.for vision. Medial from inferior colliculus of the mid brain.for hearing	crossing <ul style="list-style-type: none"> <li>controls movement of the neck muscles</li> <li>some movements like raising the arms in front of eyes.</li> </ul>	both tracts end around A.H Cells in cervical region of the spinal cord

# Crebellum

## Functions of the cerebellum:

- Control of equilibrium — mainly performed by the flocculo-nodular lobe — which is assisted by its connection to the labyrinth through the vestibular nuclei.
- Regulation of the muscle tone — is inhibitory to the muscle — the paleo-cerebellum = anterior cerebellum — is excitatory to it. — neo-cerebellum = posterior cerebellum
- Regulation of the gross involuntary movements: — through its connection with — basal ganglia — motor areas — other extra pyramidal system.
- Role of cerebellum in ballistic movement: — Most rapid movements of the body such as — movements of the fingers in typing — saccadic movements of the eyes.
- Control of voluntary movements — controlling the timing and the progression from one movement to another — rather than initiation of these movements — Mainly the function of neo-cerebellum — A-Servo-comparator function: — B-Damping function of the cerebellum: — C- Predictive function: — D- Programmer function:

## Lesions in cerebellum:

- Archi-cerebellar syndrome: — affects mainly foliuculo-nodular lobe — disturbances in equilibrium with a characteristic gait called "drunken gait" — patient walks swinging from side to side like a drunken person with wide base.
- Paleo- cerebellum Syndrome: — In which there is hypertonia — equilibrium and voluntary movements are more or less normal.
- Neo- Cerebellar syndrome (Ataxia): — affect the neo-cerebellum — characterized by: — a-Athenia — severe muscle weakness — not paralysis in the same side of lesion. — b-Hypotonia — The tendon jerk takes the characteristic "Pendular knee jerk". — because neo-cerebellum facilitates the muscle tone — c- Cerebellar ataxia: — 1.Dysmetria — 2.Dys-diadokokinesia — 3. Stacatto speech — 4.Kine tic (inte ntio n) tre mo rs — 5.Cerebellar Nystagmus — 6. Rebound phenomenon — 7. Abnormalgait, Zigzag gait, : — 8.Decomposition of movements:
