• can be divided into biologically <u>distinct regions</u>, the most important of which are the <u>peripheral</u> and <u>transition</u> zones.

Prostate— Histology

- Normal prostate contains glands with two cell layers, a flat basal cell layer & an overlying columnar secretory cell layer.
- Surrounding prostatic <u>stroma</u> contains a <u>mixture of smooth muscle</u> and <u>fibrous tissue</u>.

Prostatic disorderes can be classified as:

- Hyperplastic lesions
- Most arise in inner transition zone.
- Causes urinary obstruction. Port

Carcinomas

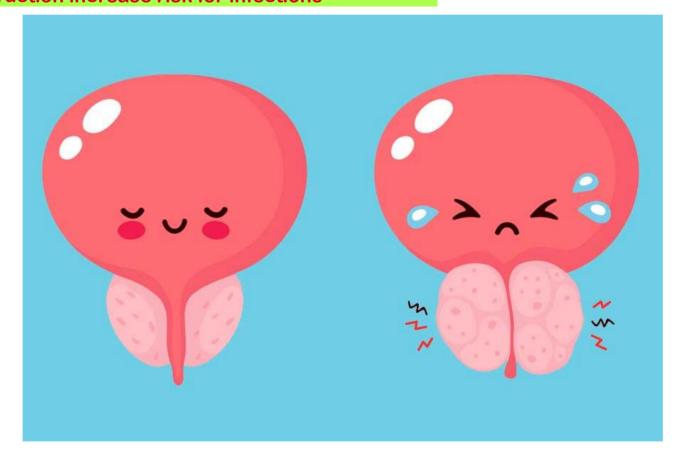

- 70%–80% arise in peripheral zones.
- Often detected by <u>rectal examination</u>

 Since its @ posterior of many and aland

Hyperplastic lesions transitioned

increase number of cells, benign, that will compress neck of urethra (leading to distension of bladder "painful condition" **obstruction increase risk for infections

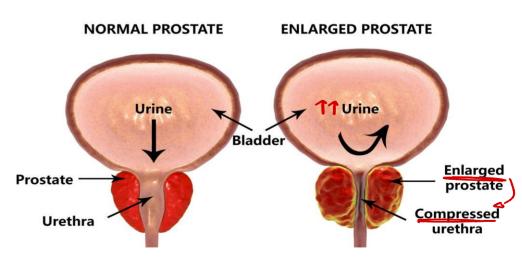

1. Benign Prostatic Hyperplasia

- An extremely common cause of prostatic enlargement by the age of 40 years.
- An important cause of urinary obstruction.
- Although the cause of BPH is incompletely understood, excessive androgen-dependent growth of stromal & glandular elements has a central role.
- Does not occur in males castrated before the onset of puberty.

neuter / removed testicles

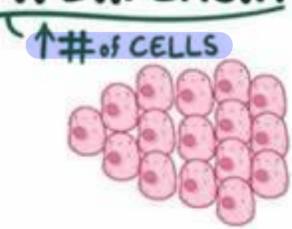

BENIGN PROSTATIC HYPERPLASIA

BENIGN PROSTATIC HYPERPLASIA (BPH)

MALIGNANT

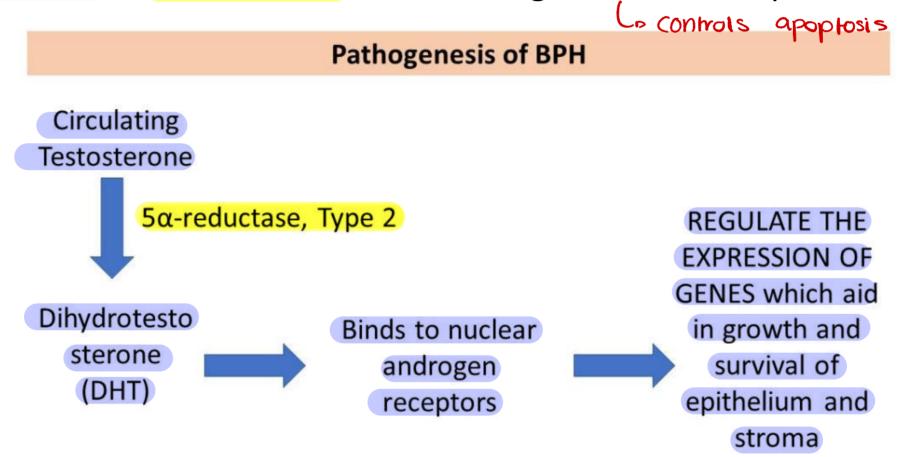

- * COMMON IN MEN OVER 50
- * OFTEN CONSIDERED & NORMAL PART of AGING

Pathogenesis

• DHT(Dihydrotestosterone)-induced growth factors act by increasing the proliferation of stromal cells & decreasing the death of epithelial cells.

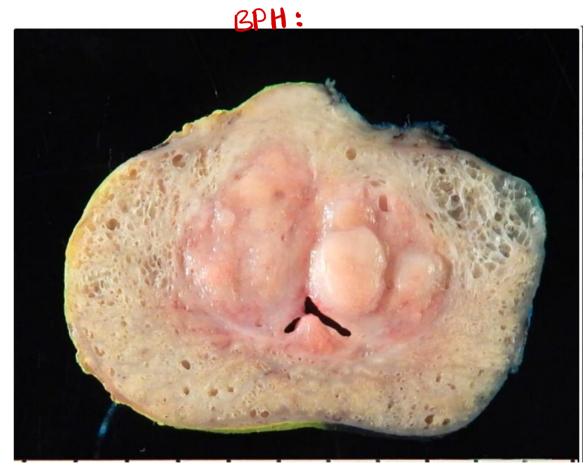

Macroscopic

Benign prostatic hyperplasia <u>nodules</u> around the urethra bulge above the cut surface in a cross section of the prostate gland.

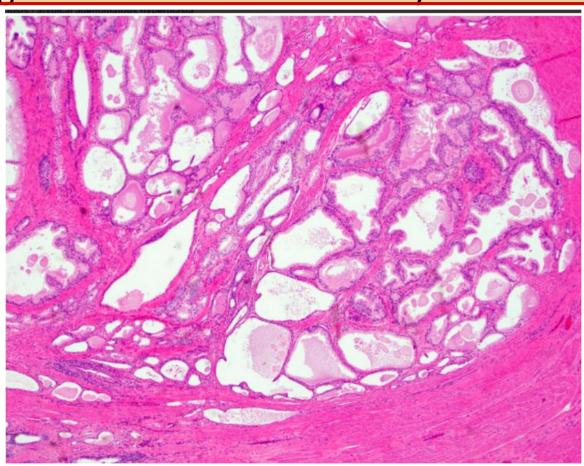

Microscopic

• Epithelial hyperplasia is characterized by nodular lesions composed of variably sized glandular structures lined by basal and secretory cells

Clinical Features

```
Symptoms:
(occur in only 10% of cases) and include:
```

- urgency, sudden need to
- frequency,
- Nocturia (with increased risk of urinary tract infections).

 Toolstrick

 Construction

 Only

 Only
- Treatment:
- Prostate
- Initial pharmacologic; agents inhibit formation of DHT.
- ❖Surgical treatment for :
- severely symptomatic cases.
- resistant to medical Rx(Transurethral resection of the prostate (TURP)).

Carcinoma of the Prostate

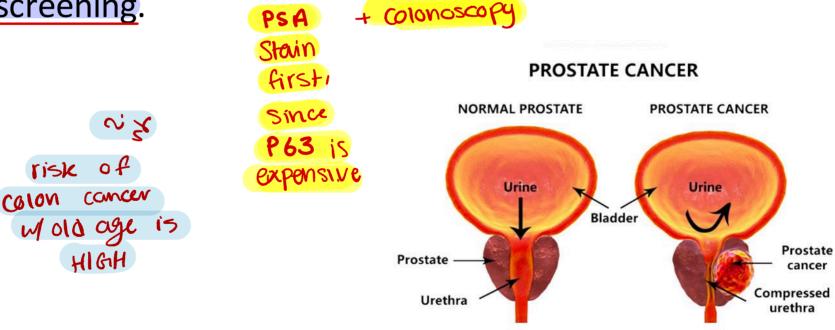

Adenocarcinoma of prostate is the most common form of cancer in men.

Age: older than 50 years.

Significant drop in prostate cancer mortality

increase detection of

disease through screening.

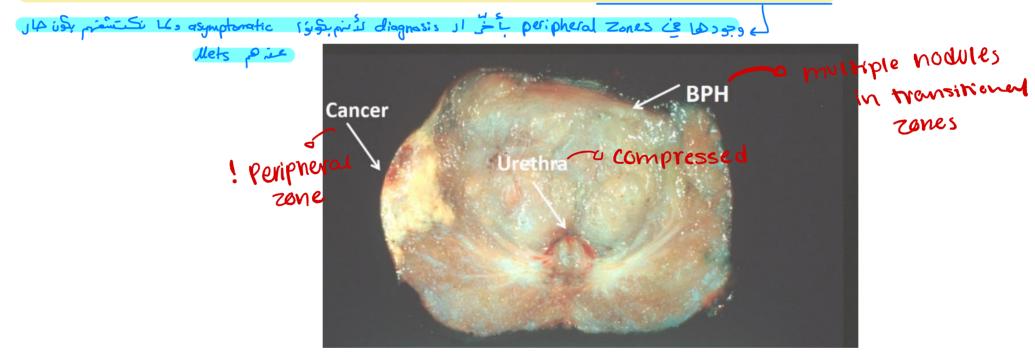

Pathogenesis

- Androgens: are of central importance; evident by
- Cancer of the prostate doesn't develop in males castrated before puberty.
- Cancers often regress for a time in response to surgical or chemical castration.
- Heredity.
- Environment:
- geographical variations that may be due to dietary variations
- Acquired somatic mutations:
- + TMPRSS2-ETS fusion genes are found in ~ 50% of cases.

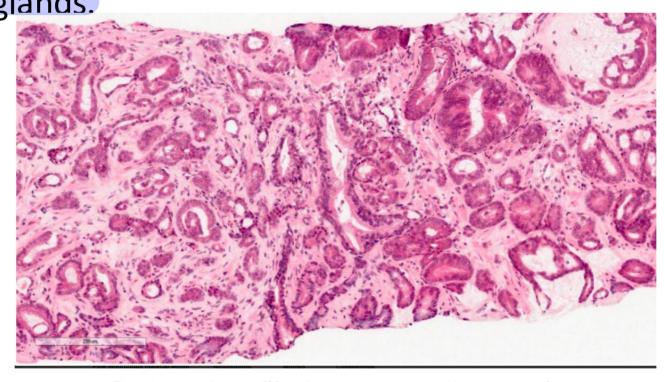

Morphology

- GROSS: firm, gray-white lesions with ill-defined margins.
- · Most tumors are multifocal. so rodio merapy
- 75 80% are posterior / posterolateral peripheral zone

Microscopically

• well-defined glands, typically smaller than benign glands and are lined by a single uniform layer of cuboidal epithelium, lacking basal cell layer seen in benign glands.

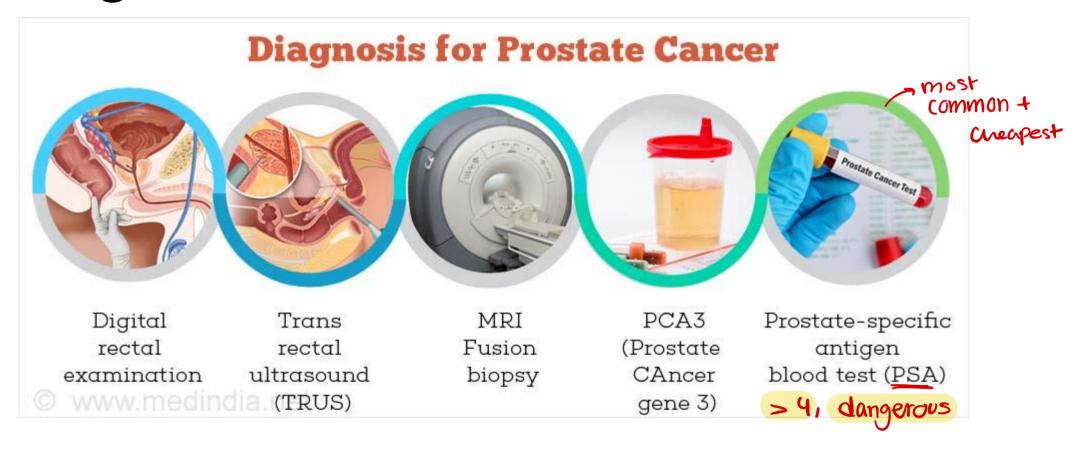

malignant

P63 stain will give a negative result

clinical features

- Generally <u>asymptomatic</u> unless locally advanced or metastatic
- Often discovered following investigation of nonspecific lower urinary tract symptoms.
- Serum screening tests: elevated prostate-specific antigen (PSA) level.
- Digital rectal examination (DRE): prostate may feel normal or may be enlarged / asymmetrical .
- Bone metastases, particularly to the axial skeleton, are frequent late in the disease and typically cause osteoblastic (bone-producing) lesions.

Diagnosis

Treatment.

• The most common treatments for clinically localized prostate cancer are radical prostatectomy and radiotherapy.

multifocal lesions

- The prognosis after radical prostatectomy is based on:
- the pathologic stage
- the margins of the resected specimens are free of tumor or not.
- Gleason grade (grading system on the basis of glandular patterns of differentiation)

cosmilarity to its original

1. Small, uniform glands. 2. More space (stroma) between glands. 3. Distinctly infiltration of cells from glands at margins. 3 Poorly differentiated Anaplastic cells with few glands. 4. Irregular masses of neoplastic cells with few glands. 5. Lack of or occasional glands, sheets of cells.

Stage I - the cancer is small and only in the prostate Stage II - the cancer is larger and may be in both lobes of the prostate but is still confined to the prostate Stage III - the cancer has spread beyond the prostate to close by lymph glands or seminal vesicles Stage IV - the cancer has spread to other organs such as the bone and is referred to as metastatic cancer. If prostate cancer spreads, or metastasizes, to the bone, you have prostate cancer cells in the bone, not bone cancer

For a detailed description of each stage, see the information at the bottom of the page. Detailed Staging, adapted from www.cancer.gov.
