# Development of Umbilical Cord

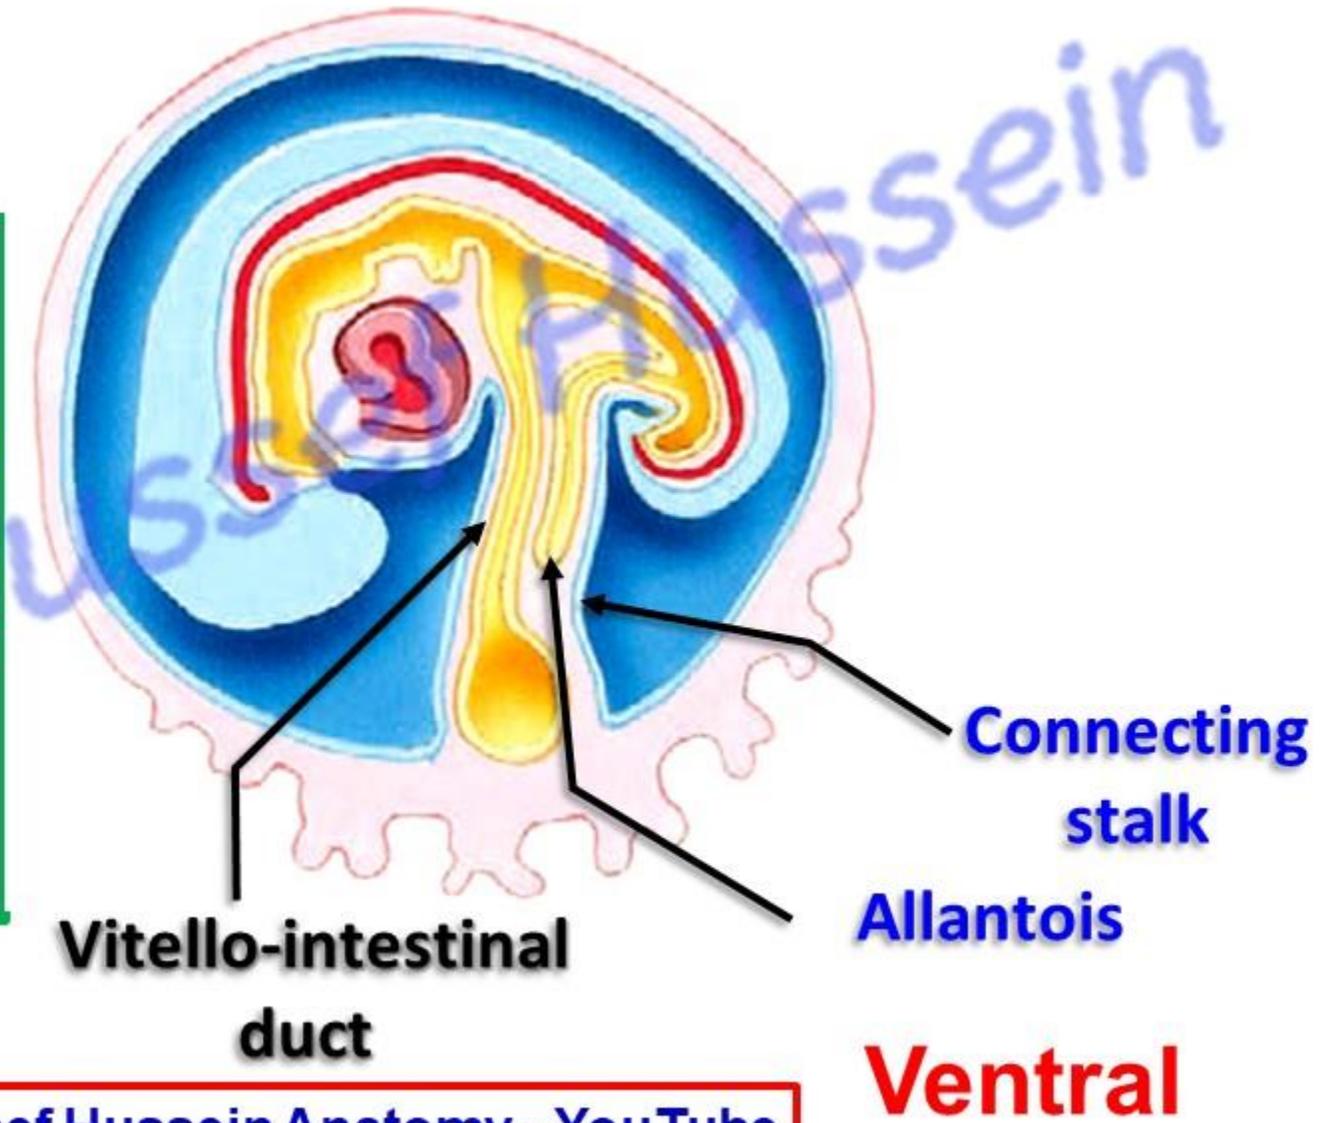

dr\_youssefhussein@yahoo.com

- It is a cord-like structure connects the placenta (fetal surface) with the umbilicus of the fetus

## \*\* Formation of the primitive umbilical cord

- As the results of the tail folding, The connecting stalk (**Future umbilical cord**) becomes ventral to embryo and containing **Allantois** and **Vitellointestinal duct**

[dr\\_youssefhussein@yahoo.com](mailto:dr_youssefhussein@yahoo.com)

[Prof. Dr. Youssef Hussein Anatomy - YouTube](#)

## \*\* Formation of the primitive umbilical cord

**1- Vitello-intestinal duct (VID) between midgut and definitive yolk sac** and surrounded by 2 vitelline arteries and 2 vitelline veins.

**2- Loops of intestine** (physiological hernia) in the *extra-embryonic coelom*.

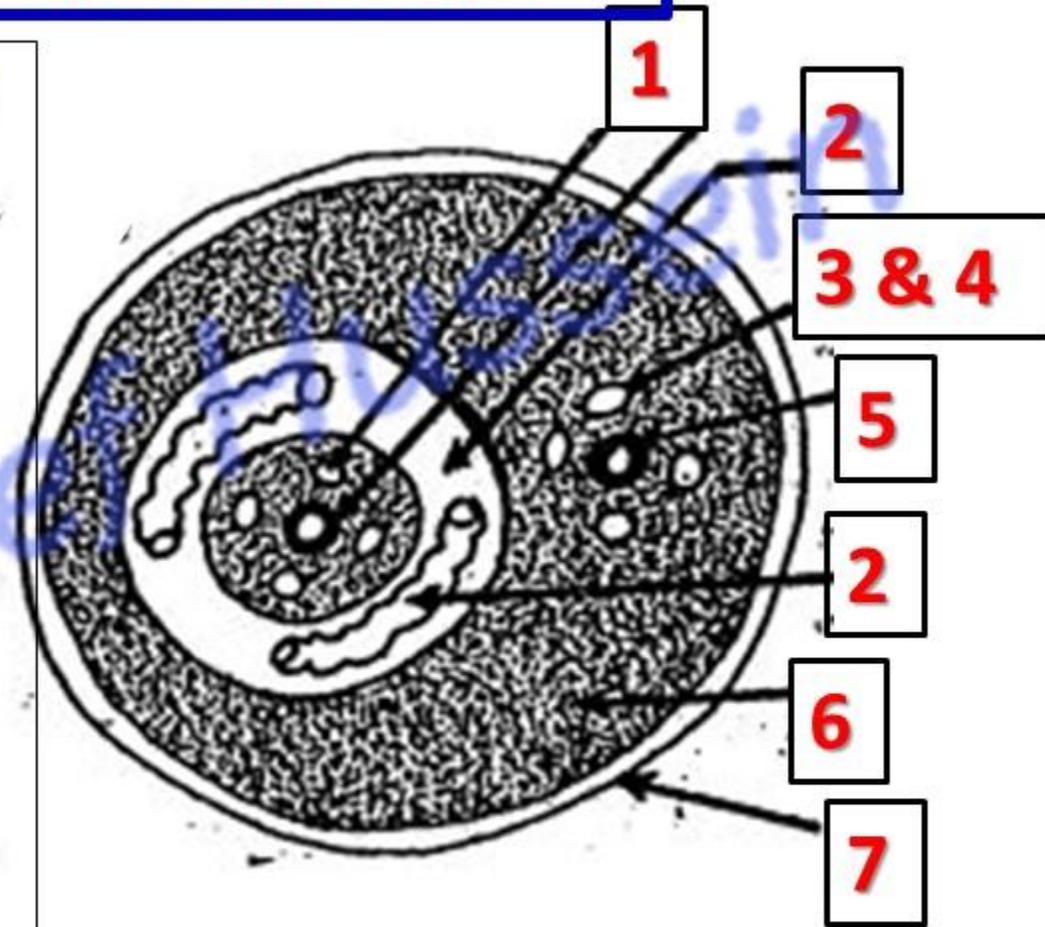

**3- 2 umbilical arteries** carry **non-oxygenated** blood from the fetus to the mother.

**4- 2 umbilical veins** carry **oxygenated** blood to the fetus.

**5- Allantois (urachus)** small diverticulum from cloaca and extends into the connecting stalk.  
- It connects the apex of the urinary bladder with the umbilicus.

**6- Extra-embryonic mesoderm.**

**7- It is covered by amniotic membrane.**

# Definitive of Umbilical Cord

Remnant of allantois

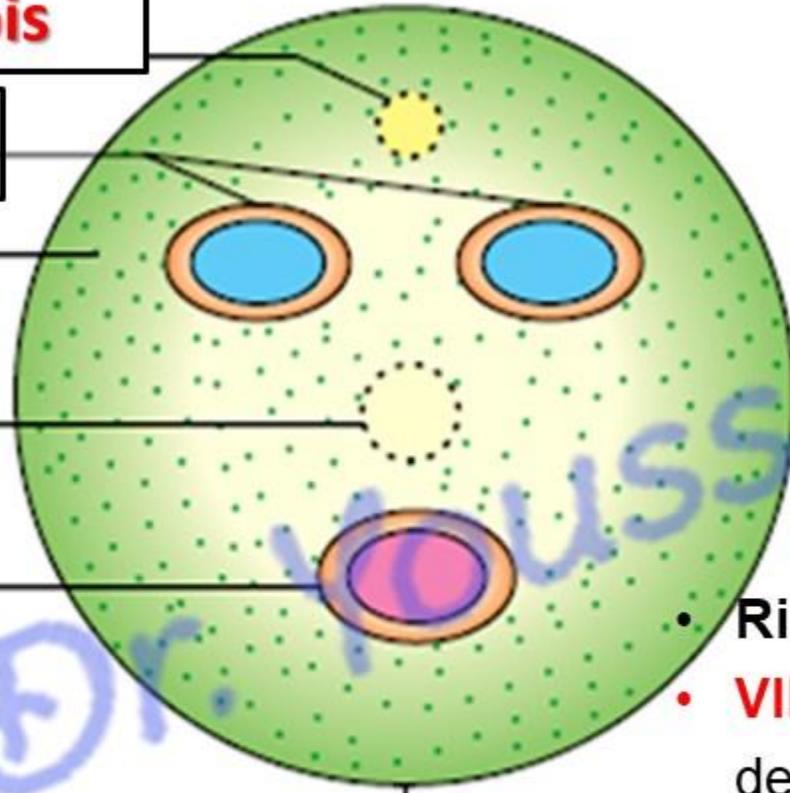

2 Umbilical arteries

Wharton's jelly

Remnant of VID

Left Umbilical vein

Amnion

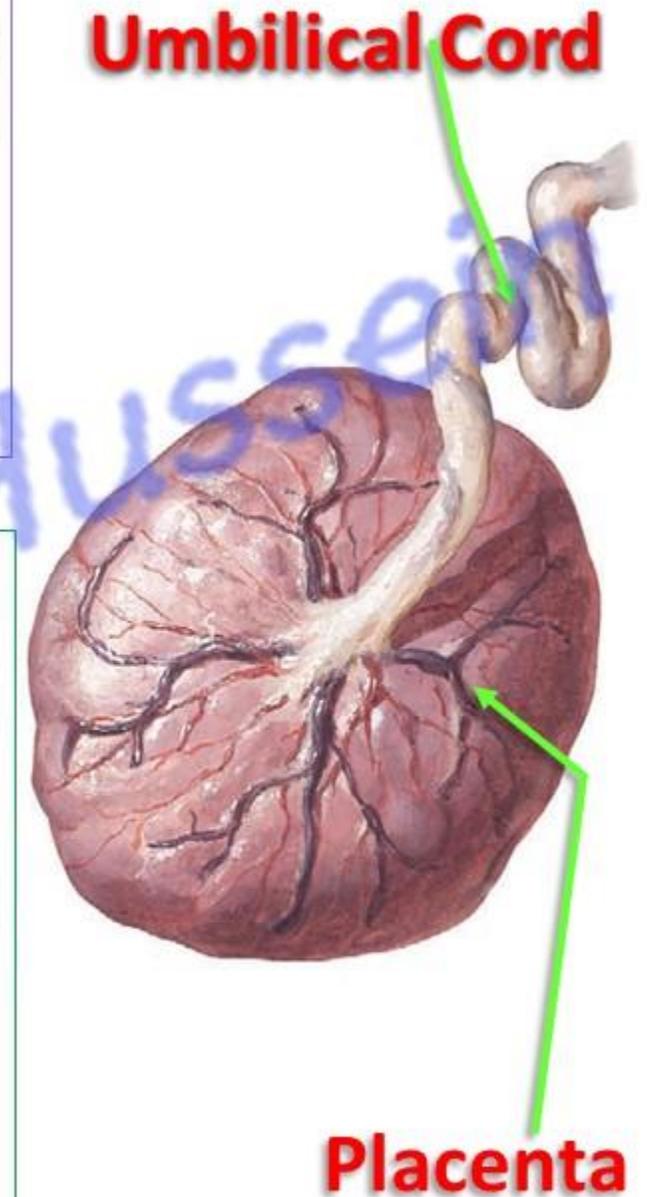

- **2 umbilical arteries** (Right & Left).
- **Left umbilical vein.**
- These structures are embedded in a jelly like material called **Wharton's jelly.**
- It is covered by **amniotic membrane.**

- **Right umbilical vein** is obliterated.
- **VID and vitelline vessels** obliterated and degenerated.
- **Allantois (urachus)** obliterated and forms **median umbilical ligament** of urinary bladder.
- **Loops of intestine** return to abdominal cavity.
- **Extra-embryonic coelom** is closed.

- The umbilical cord has natural twists (false knotting) because umbilical vein is longer than umbilical arteries
- At Full-term Length: 50–55 cm.  
Breadth: 1–2 cm

[Prof. Dr. Youssef Hussein Anatomy - YouTube](#)

- Changes of umbilical cord after labor
- Left umbilical vein is obliterated and forms ligamentum teres of the liver.
- 2 umbilical arteries are obliterated and form 2 medial umbilical ligaments of the urinary bladder.
- Allantois is obliterated and forms median umbilical ligament of the urinary bladder
- VID is obliterated and degenerated

- **Congenital anomalies of the umbilical cord**

1) **Very long cord:** more than one meter.

- It may surround the neck of the fetus leading to death.
- It may turn around limb of the fetus leading to its atrophy.
- Cord prolapse in the vagina during childbirth

2) **Very short cord:** less than 30 cm.

- It limits the movement of the fetus.
- It leads to early separation of the placenta leading to bleeding.

3) **Congenital umbilical hernia:** failure of reduction of the intestine.

4) **True Knotting of the cord:** leading to interfere with the blood supply of the fetus.

5) **Double or triple cord.**

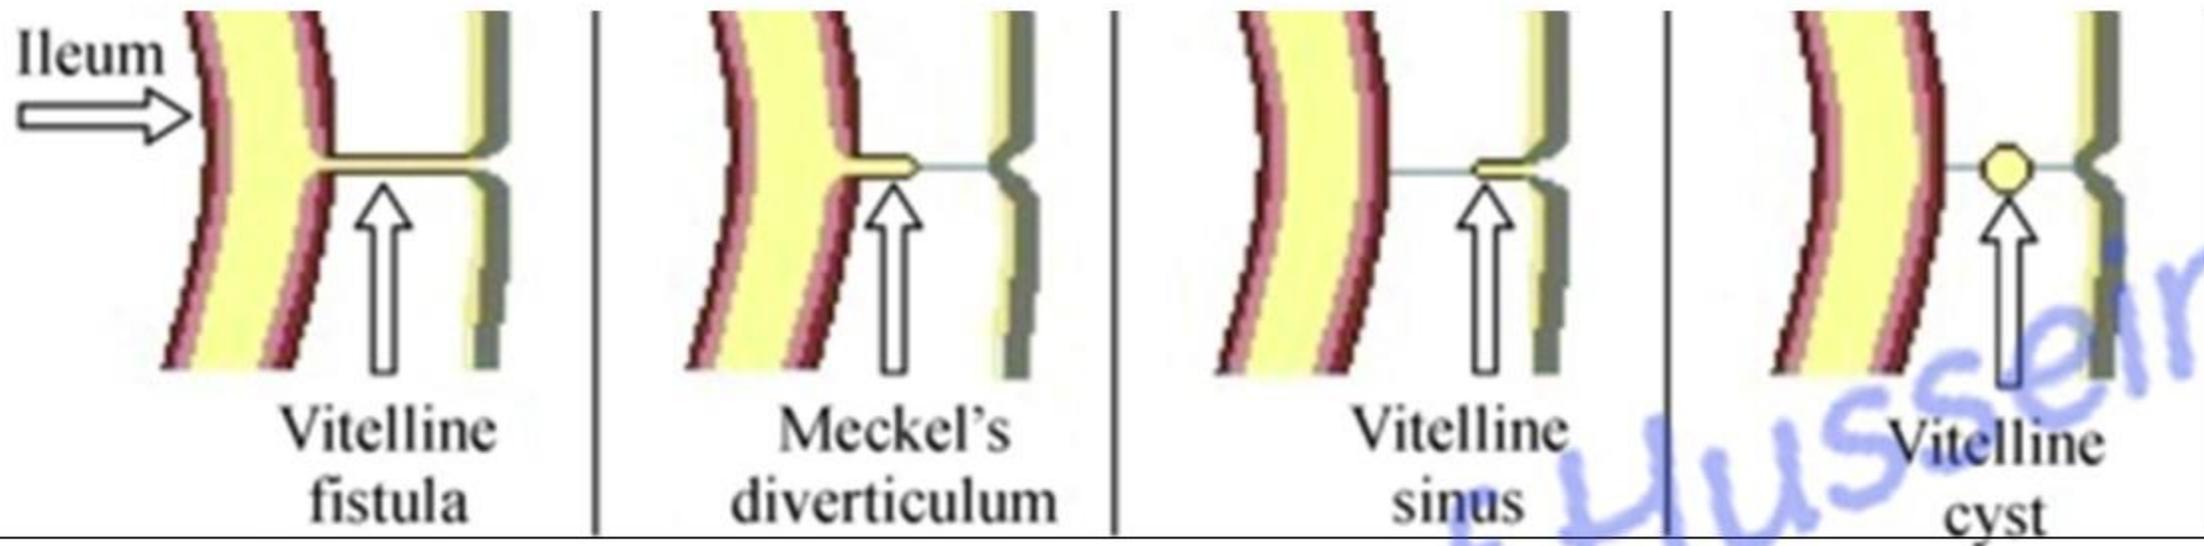

## 6) Anomalies in the attachment of the cord:

- a- **Battledore** <sup>هامشية</sup> **placenta**, attached to the **margin** of the placenta.
- b- **Velamentous** <sup>غلافي</sup> **placenta**, attached to the fetal membranes.

## 7) Anomalies in the allantois (urachus):

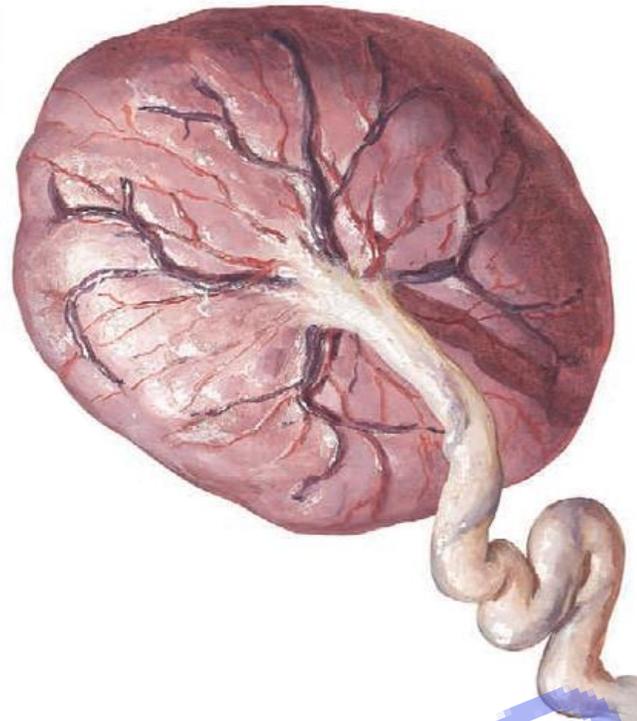

- a- **Urachal fistula**: persistence of the urachus. It leads to discharge of urine from the umbilicus of the fetus.
- b **Urachal cyst**: persistence of the **middle** part.
- c- **Urachal sinus**: persistence of the **distal** end.

## 7) Anomalies in the vitellointestinal duct (SEE yolk sac)

**\*\* Congenital anomalies of Vitellointestinal duct:**

- i) **Vitelline fistula (patent VID):** persistence of the duct leading to discharge of the intestinal contents through the umbilicus.
- ii) **Meckel's diverticulum,** persistence of the **proximal** end of the duct.
- iii) **Vitelline sinus:** persistence of **distal** end of the duct leading to discharge mucus from the umbilicus.
- iv) **Vitelline cyst:** persistence of the **middle** part of the duct.
- v) **Fibrous band,** The duct completely fibrosed and persistence leading to Volvulus and intestinal obstruction.

# Development of Placenta

Prof. Dr. Youssef Hussein  
[dr\\_youssefhusssein@yahoo.com](mailto:dr_youssefhusssein@yahoo.com)

[Prof. Dr. Youssef Hussein Anatomy - YouTube](#)

The placenta consists of two components: **maternal** and **fetal**.

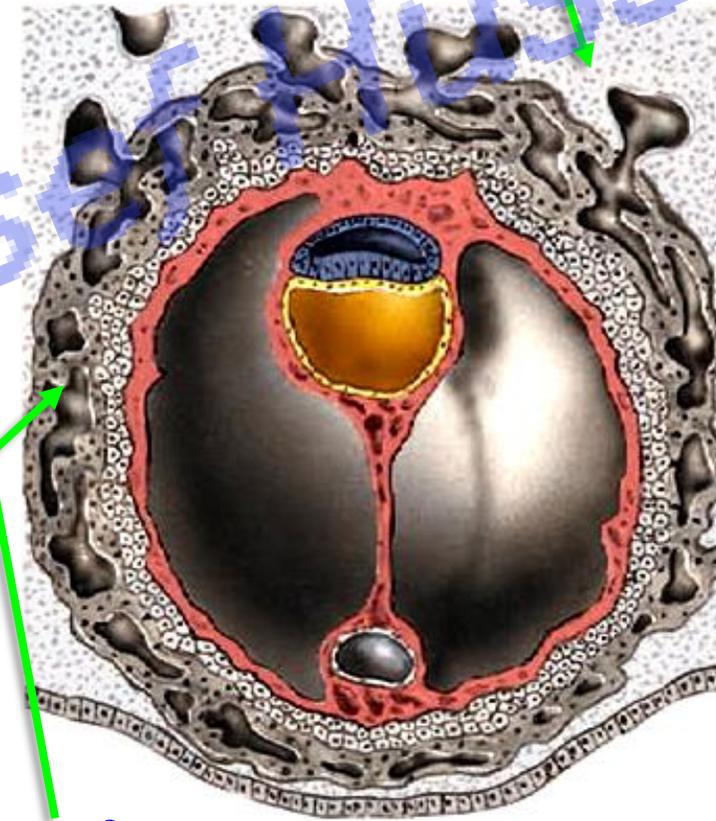

A- The **fetal** part develops from **chorion frondosum**

B- The **maternal** part develops from the **decidua basalis** (**endometrium** of the uterus after fertilization and implantation)

The **placenta** is the only organ in the body that develops from two different individuals, fetus (chorion) and mother (endometrium)

## Parts of Placenta

Endometrium

Chorion

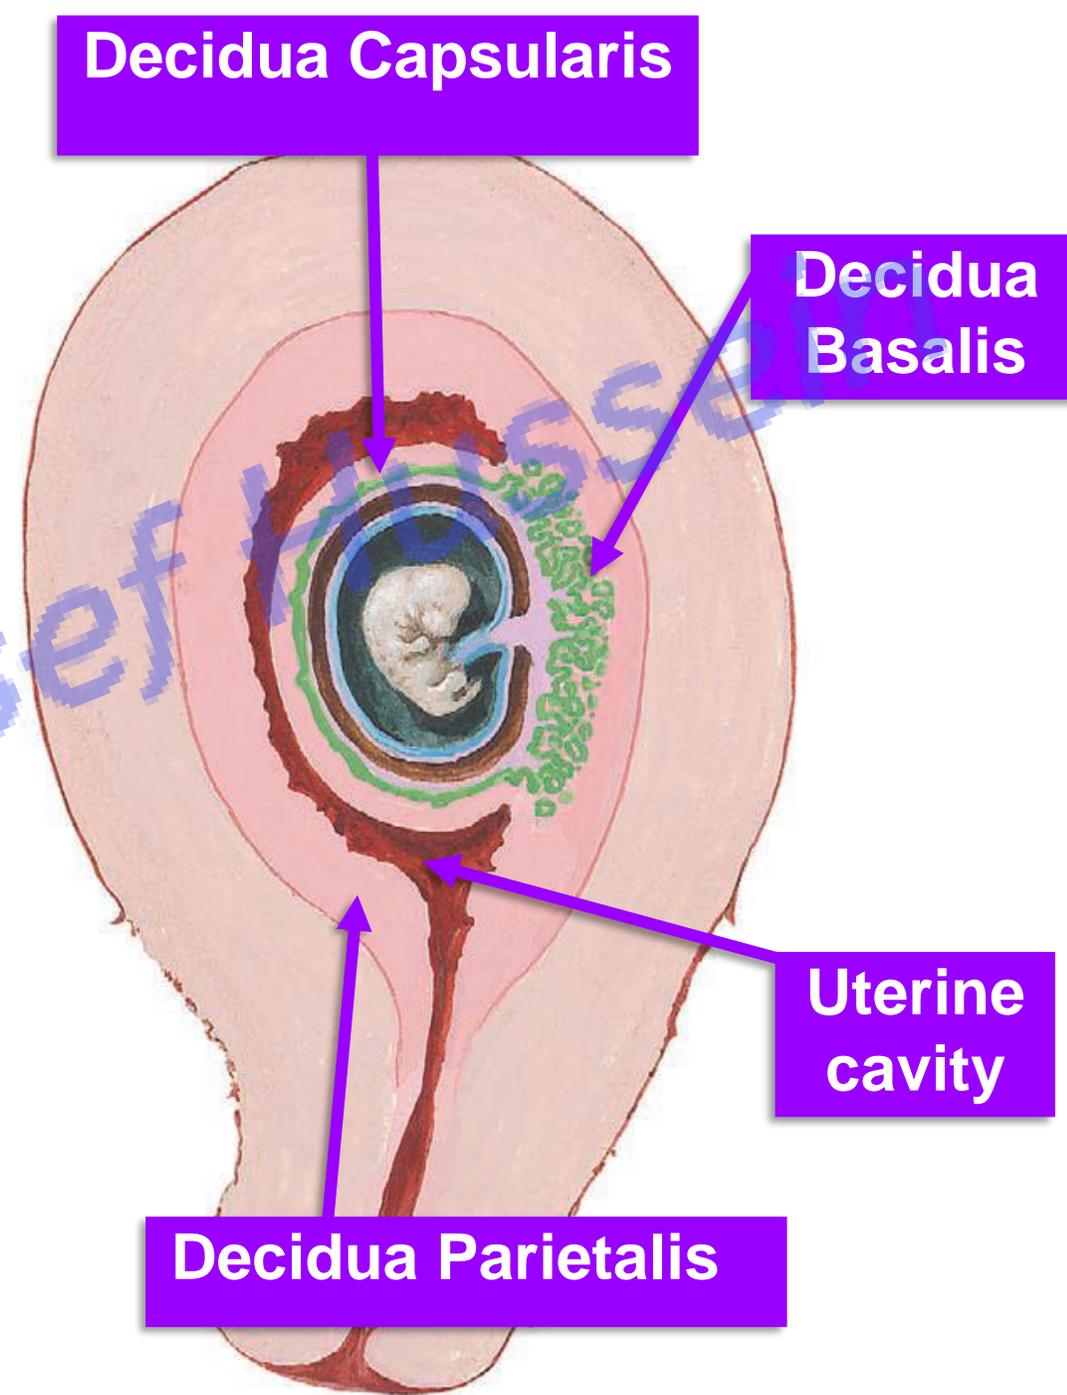

[dr\\_youssefhussain@yahoo.com](mailto:dr_youssefhussain@yahoo.com)

- **Development of decidua (Maternal part)**

- a- The endometrium becomes thicker and more vascular.
- b- Its glands become highly tortuous and filled with secretions.
- c- It contains decidual cells characteristic of pregnancy.

- **Parts of decidua**

- **Decidua basalis:** deep to the embryo (between blastocyst and myometrium). It forms the maternal part of placenta.
- **Decidua capsularis:** covers the blastocyst, later on disappear.
- **Decidua parietalis:** the rest of endometrium that lines uterine cavity, later on disappear.

# Development of Chorionic Villi

[Prof. Dr. Youssef Hussein Anatomy - YouTube](#)

# Chorionic Vesicle

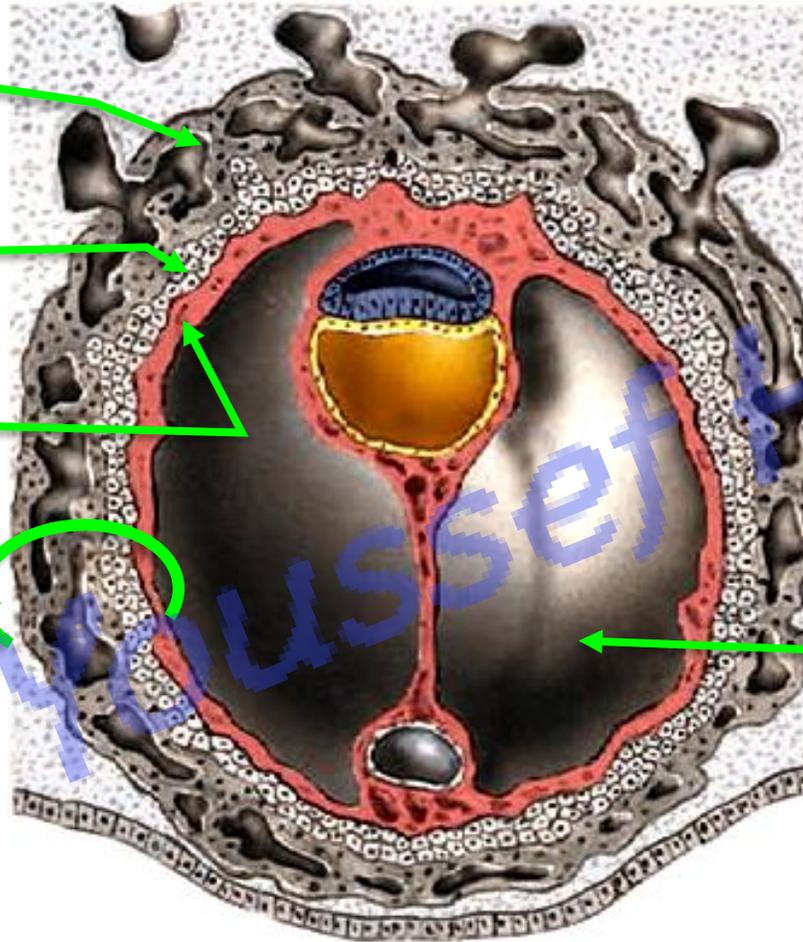

Syncytiotrophoblast

Cytotrophoblast

Somatic layer of  
E. E. mesoderm

Chorion

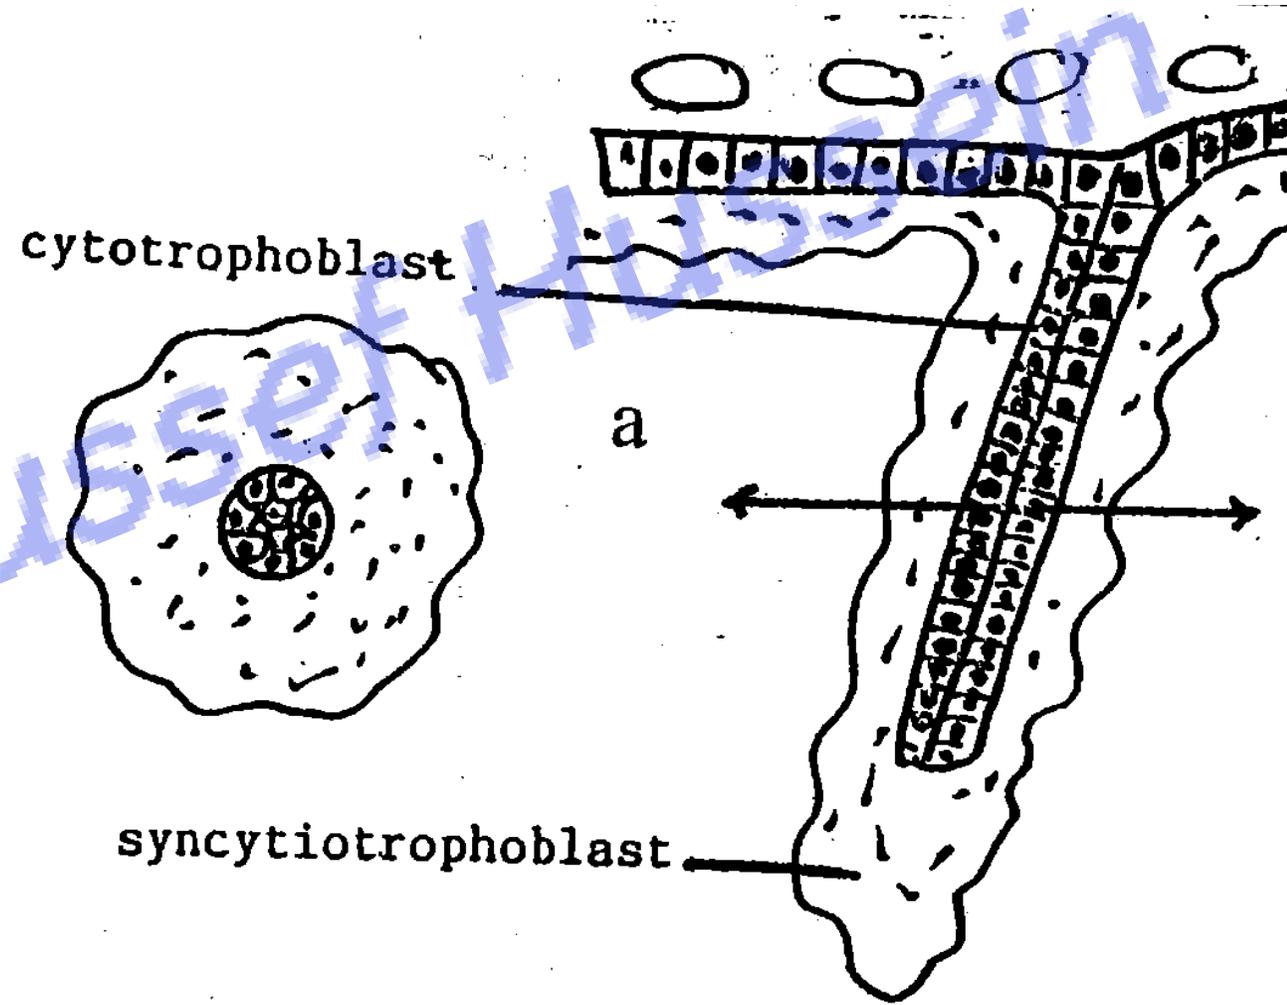

Chorionic  
cavity

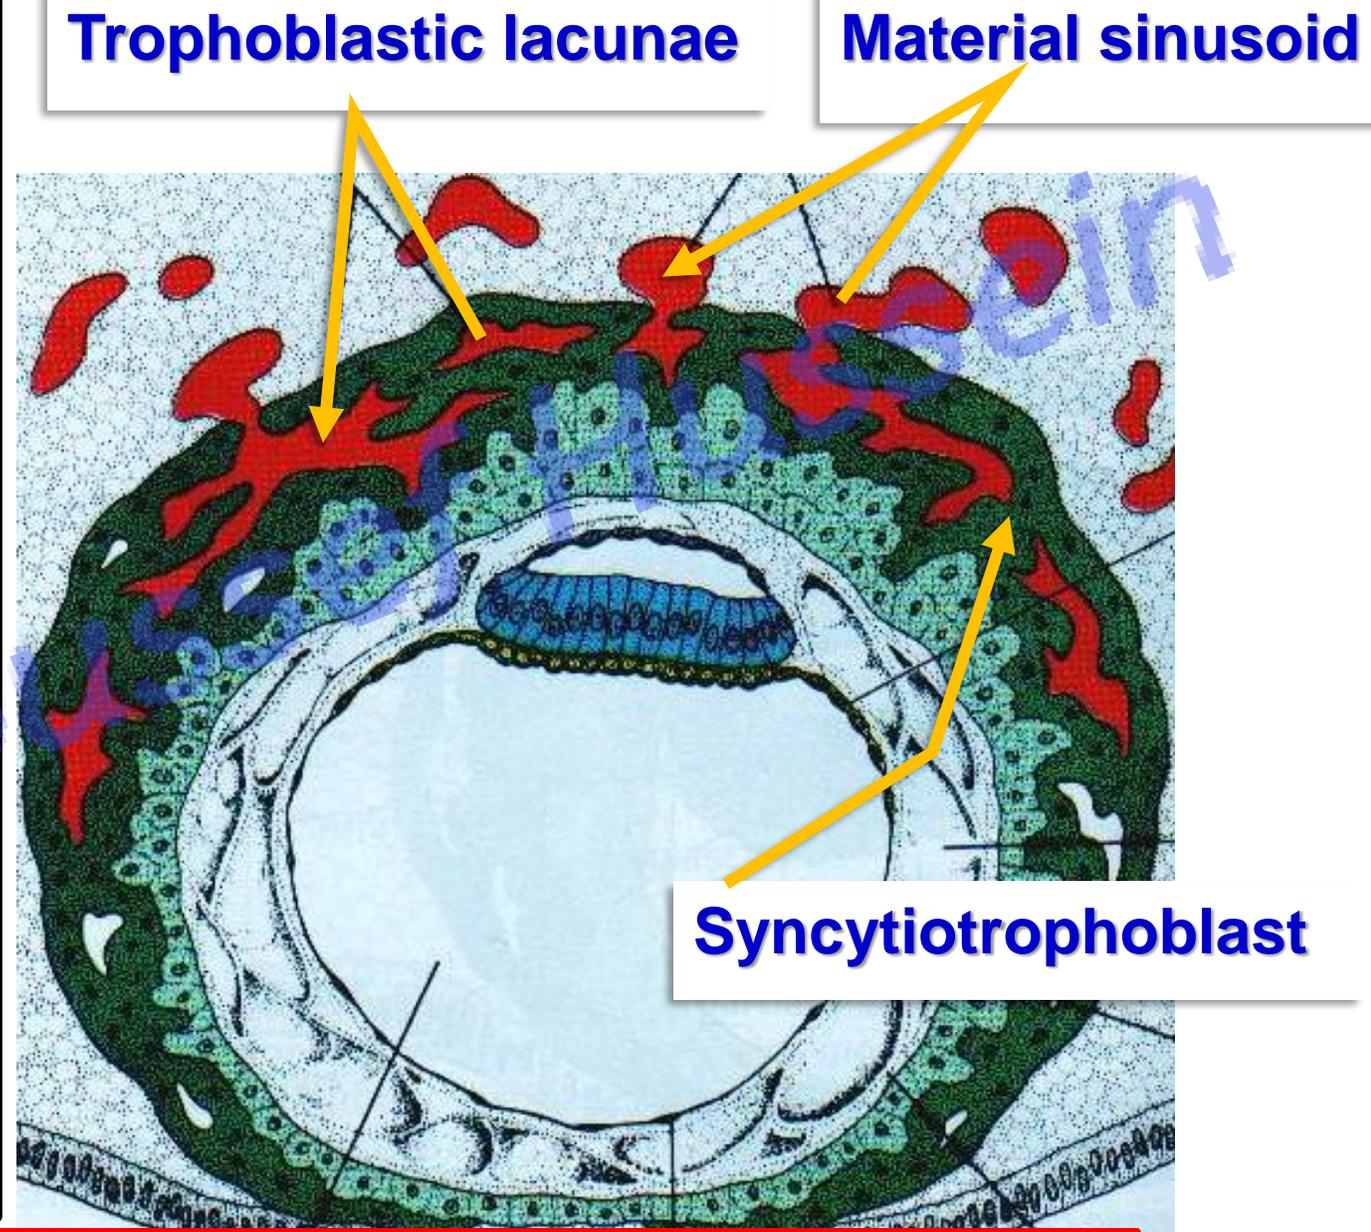

- By the end of 2<sup>nd</sup> week, The blastocyst is called **chorionic vesicle** having large cavity called chorionic cavity
- The Chorion (wall) is formed by three layers: 1) Syncytiotrophoblast.  
2) Cytotrophoblast. 3) Somatic layer of extraembryonic mesoderm.

- **Primary chorionic villi :**
  - The **syncytiotrophoblasts** form finger-like projections.
  - The **cytotrophoblasts** migrate into center of the projections.
  - The **villi** are separated from each other by spaces called **lacunae** filled with maternal blood due to erosion of the uterine vessels by syncytiotrophoblast.

## Primary chorionic villi

- **Trophoblastic lacunae** appeared in syncytiotrophoblast at embryonic pole of the disc
- The syncytiotrophoblast cells **penetrate** (phagocytosis) deeper into maternal endometrium and **invade its capillaries**
- The lacunae become **filled with maternal blood**
- **S**o, maternal blood begins to flow through **lacunar system** of trophoblast and this is called **uteroplacental circulation.**

# Secondary chorionic villi

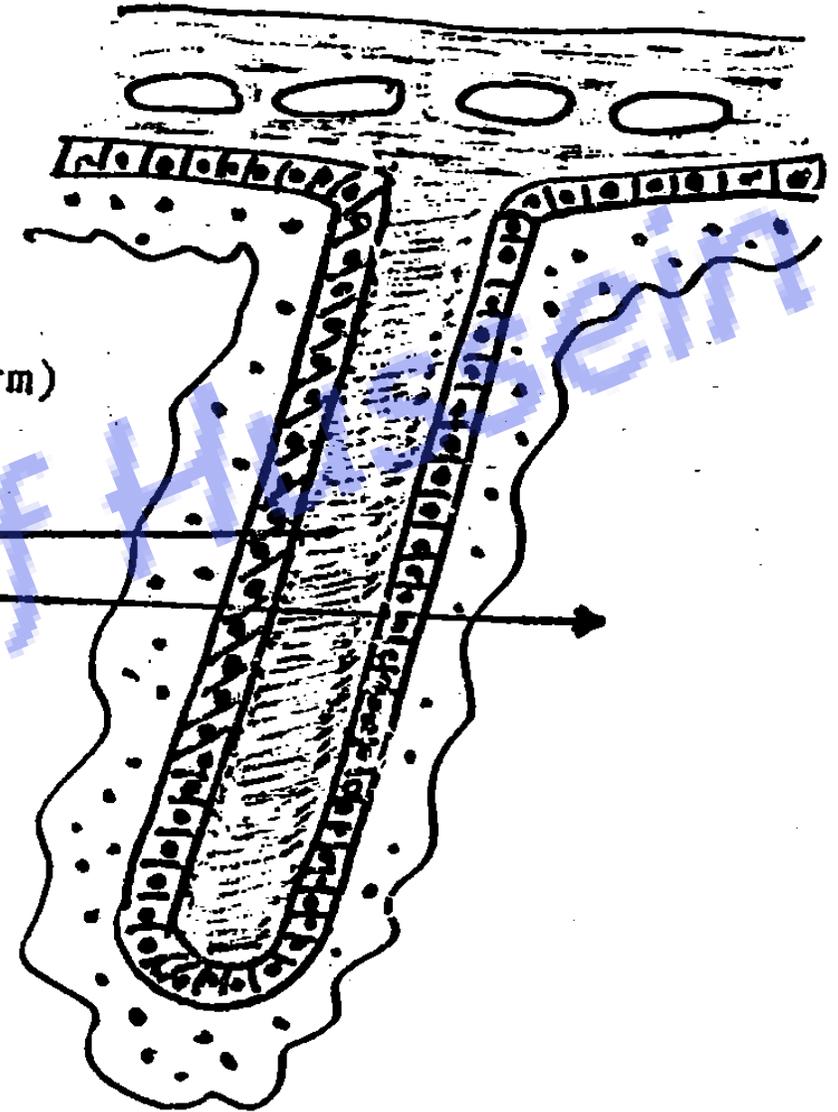

dr\_youssefhussein@yahoo.com

Secondary villus (has a core of mesoderm)

extra-embryonic  
mesoderm (core of  
the villus).

b  
syncytiotrophoblast

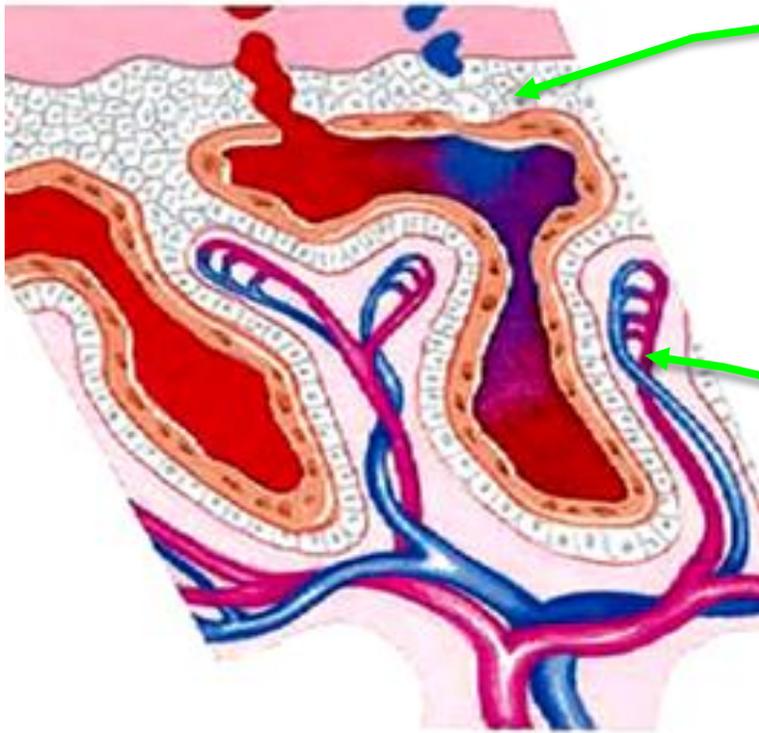

- **Secondary chorionic villi**
- The **extra-embryonic mesoderm (EEM)** proliferates and migrates into the center of the cytotrophoblastic cells.

# Tertiary chorionic villi

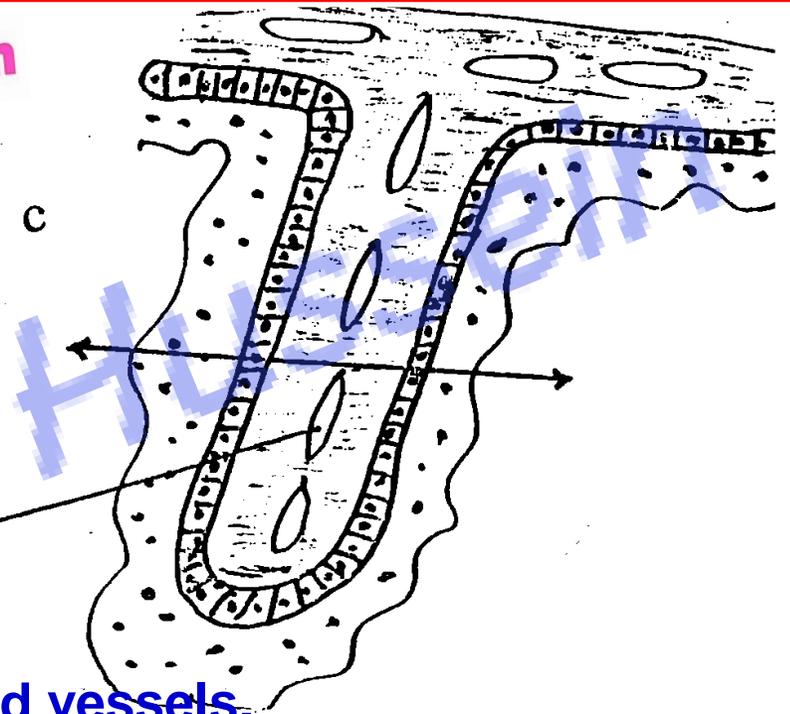

Shell

dr\_youssefhussein@yahoo.com

Fetal blood vessels

blood vessel in the mesodermal core.

## • Tertiary chorionic villi

- The cells of the **extra-embryonic mesoderm** give rise to fetal **blood vessels**.

N.B: The cytotrophoblast cells of the apical region pierce the syncytiotrophoblast cells to meet and fuse with the adjacent one forming **cytotrophoblastic shell** to prevent further erosion of the endometrium by the syncytiotrophoblast and fixes all the villi in the decidua (**Anchoring villi**).

## Fate of the chorionic villi

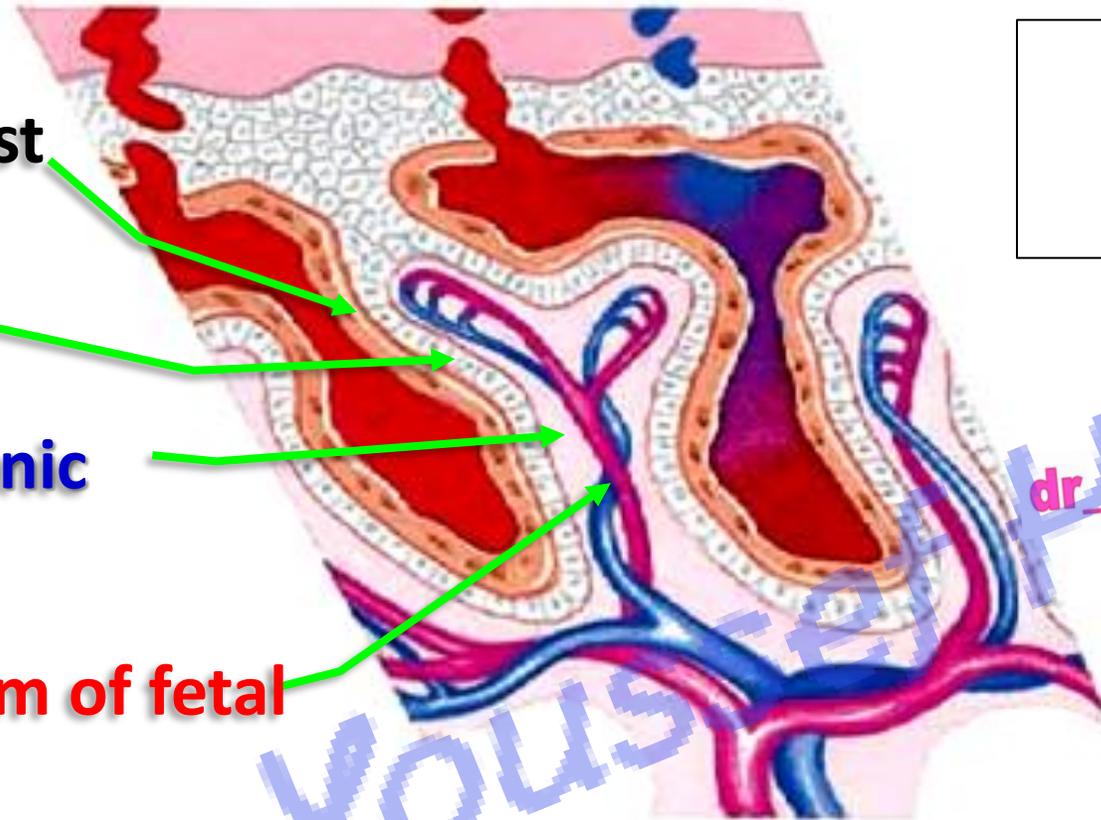

- The villi related to decidua basalis called **chorion frondosum** and forms fetal part of the placenta
- The villi related to the decidua capsularis called **chorion laevae** and later on degenerated.

[dr\\_youssefhussein@yahoo.com](mailto:dr_youssefhussein@yahoo.com)

# Placental barrier

## Placental barrier (Membrane)

dr\_youssefhussein@yahoo.com

1- Syncytiotrophoblast

2- Cytotrophoblast

3- Extraembryonic  
mesoderm

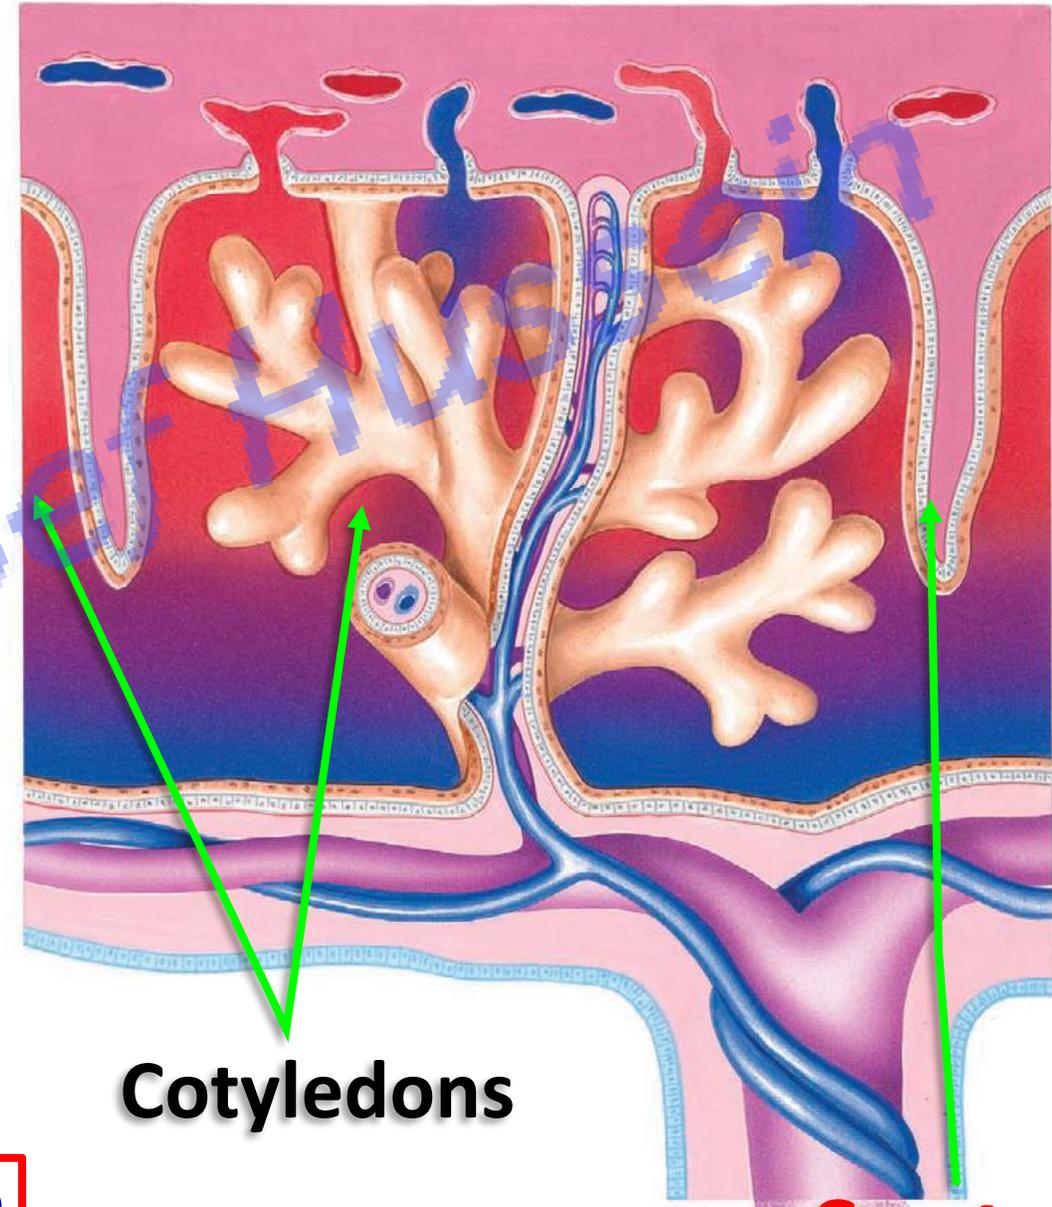

4- Endothelium of fetal  
blood vessels

- In early pregnancy, the **placental membrane** is made up of **four layers**, its thickness is **about 25 micron**
- After the **3<sup>rd</sup> month**, the nutritional demands increase so the placental membrane becomes thin to increase the efficiency of transport of nutrients, its thickness is **about 1-2 micron**. It is made of **two layers syncytiotrophoblast and endothelium of the fetal blood vessels**

# Lobulation of Placenta

## \*\* Development of decidual septa:

- The **decidua basalis** forms many **septa** that protrude into the **intervillous spaces** aiming to increase the surface area of the decidua.
- These septa divide the placenta into 15-20 lobes called **cotyledons** الفلقات.

Cotyledons

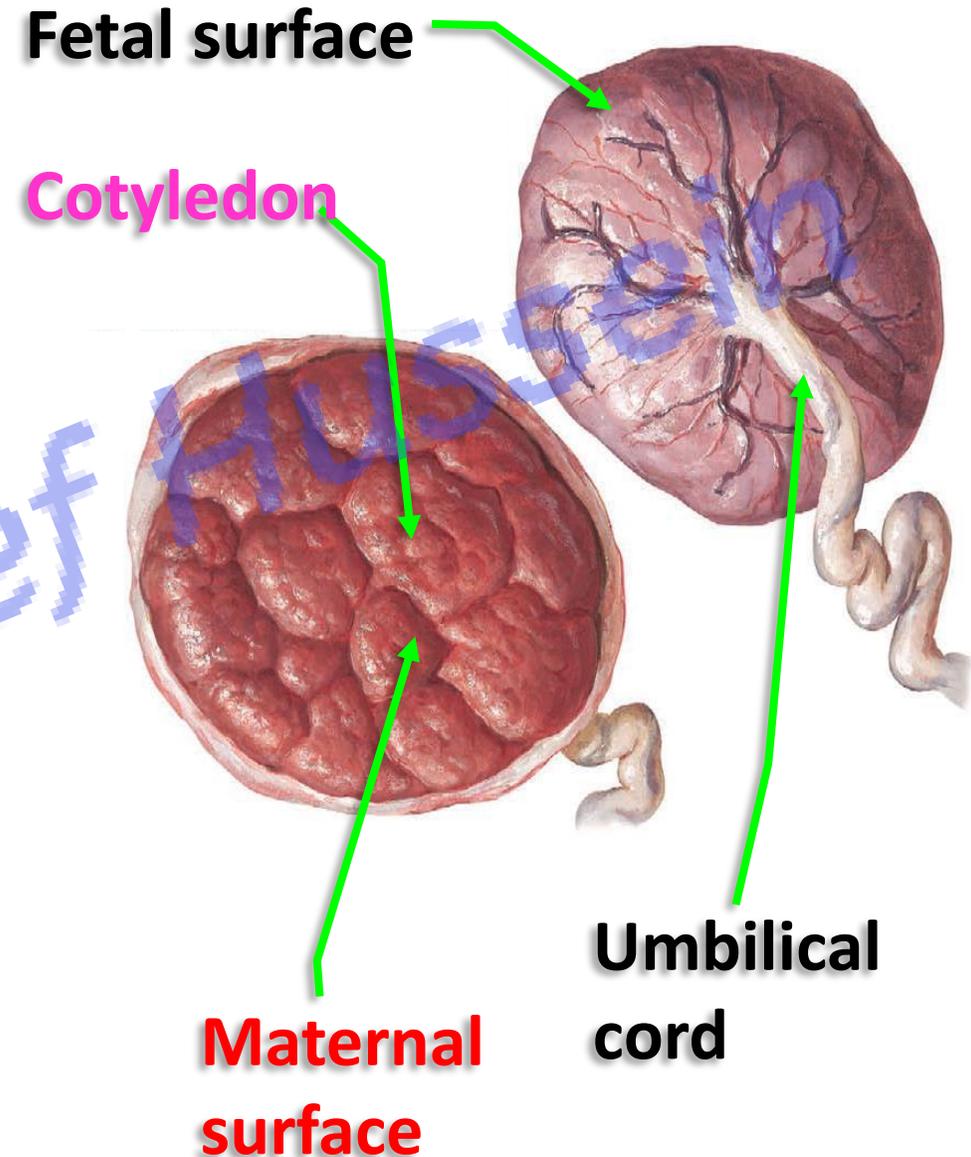

Septa

## Morphology (Gross features)

- **Shape**; disc shaped.
- **Diameter**; about 15-20 cm.
- **Weight**: about 500 gm at birth.
- **Thickness**; its center about 3 cm and its margins about 1 cm
- **Surfaces**

**A- maternal:** Rough. It is segmented into 15-20 lobes (cotyledons). الفلقات

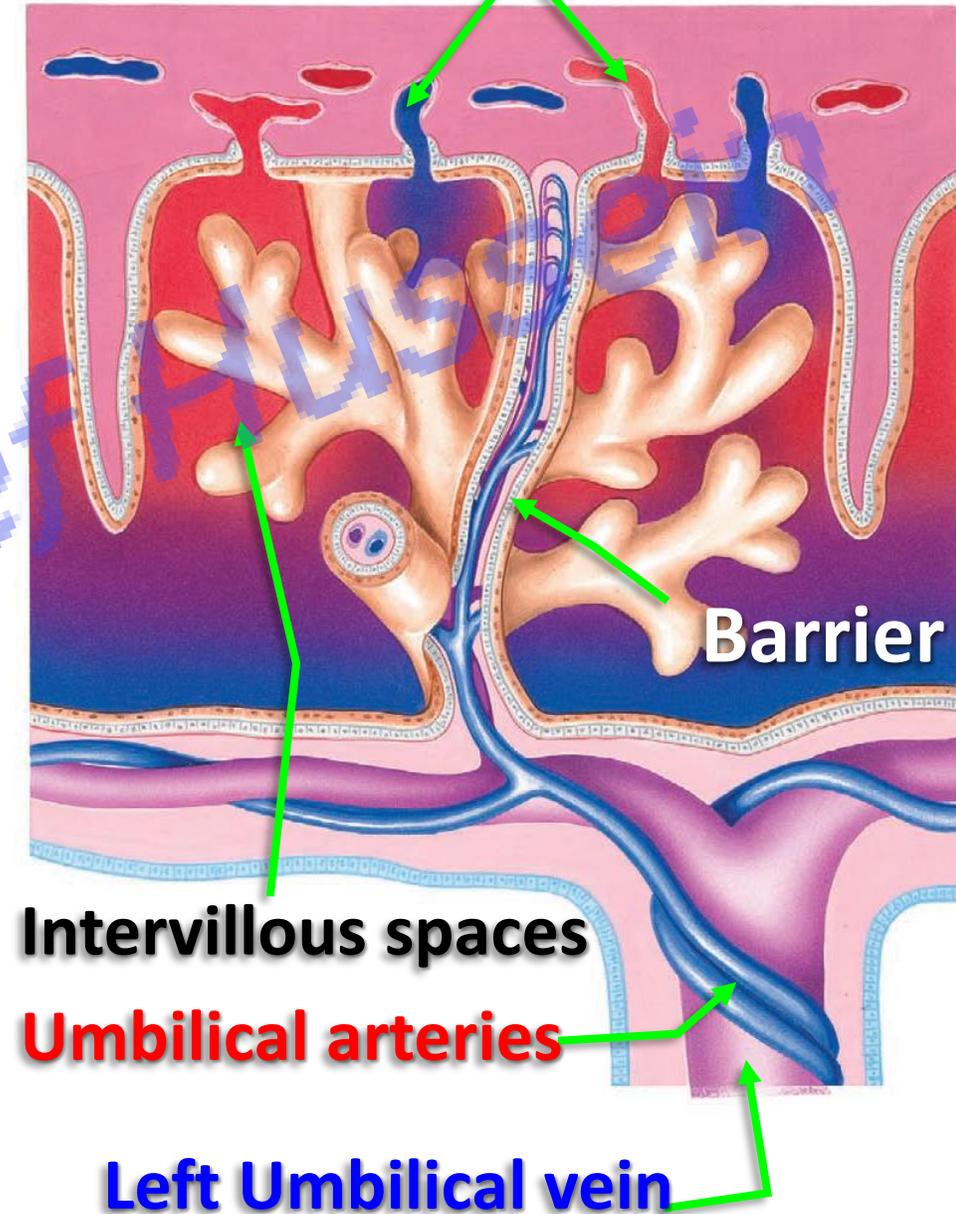

**B- Fetal:** Smooth and covered by amniotic membrane. The umbilical cord attached to the center of the fetal surface.

- **Placental circulation:**

- The fetal non oxygenated blood reaches to the placenta by **2 umbilical arteries** → where gas exchange occurs with the maternal blood in the **intervillous spaces** through **spiral arteries and veins** of the decidua basalis.
- Exchange between the 2 blood streams occurred across the **placental barrier**.
- The oxygenated blood returns to the fetus by **left umbilical vein**.

## Spiral arteries & veins
